Hi Bill,

According to the AARP, the grey-hairs outnumber the youngsters for
cellular phone connectivity - by a long shot.

>

Hi Nick,

What you cite are reasons not excuses. CPUs are in metal boxes or in
FCC compliant designs that insure reduced emissions (telephones are in
plastic boxes optimized to emit - obviously). If there is any danger
it comes from fields coming from the computer boob tube - however
these frequencies (the base frequencies) are orders of magnitude (
1/10000th) below the lowest one you cite. And yes, frequency matters.
Higher frequency suggests shorter wavelength, a standing man is nearly
1/4 wavelength tall at 10M and is in danger of being a dummy load to
near fields. Higher frequencies lead to the obvious where fingers
become meaningfully sized in relation to wavelength.

The comparison between cellular and cordless phones omits discussion
of the range of either, and hence the power emitted to perform the
function. If one wishes to weigh risks, here too less power leads to
the obvious conclusion that there is correspondingly less risk of
injury.

4348. Re: Vertical or horizontal antennas for 80m DX?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-16 17:40:15 UTC
From: richardharrison@webtv.net
Message-ID: <13599-3A3BA8FF-50@storefull-111.iap.bryant.webtv.net>
Source record: 174546

From page 817 of Terman`s "Electronic and Radio Engineering":

"With vertically polarized waves and earth having good conductivity, the height at which ground-wave action ceases to dominate and ray action begins to be most important is in the order of one or two wavelengths. ---"

"With horizontally polarized waves the critical height below which ground-wave action predominates and above which space-wave action takes over is less than a tenth of a wavelength for very poor conducting earth, and even less for good earth and sea water."

Ground-waves are useless for ionospheric propagation. Space-waves reach the ionosphere for reflection over long distances.

It is no wonder that the world`s shortwave broadcasters usually employ horizontal antennas for long distance propagation. Array drivepoints are usually located about 1/2-wavelength above ground.

Best regards, Richard Harrison, KB5WZI

4349. TUNE dipole with MFJ-249?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-16 17:43:36 UTC
From: ham_guy@webtv.net
Message-ID: <23599-3A3BA9C8-47@storefull-137.iap.bryant.webtv.net>
Source record: 174545

Hi.. I need to get some advice here. I'm going to put up a 20 meter dipole and feed it with ladder line. However, my MFJ-249 only has a connection for a coax coupler.

My plan (for the lack of a better one):
1. Pull the dipole partially up, so I can still reach the ends and middle feedpoint with a ladder.
2. Attach a temporary coax lead to the antenna feedpoint and check the resonant Q.
3. Trim the ends to get the desired resonant Q.
4. Remove the coax and the analyzer and attach the ladder line.
5. Pull the antenna to its full height and hope the difference in height and the difference in the antenna feed do not seriously degrade the tune up.

This seems to me that it has lots of room for error. Since people have been doing this for years, there must be some better method. Any tips, hints and kinks you know of? Thanks, JJ

Hi Mark,

You don't have to settle for a label libel when honest research is
already available.

Today's headline in Seattle papers (which broke this news nationwide):
"Asbestos death toll nation's worst"
which is responded to by the commercial interest (W.R. Grace) thusly:
"... some of these irresponsible numbers that were thrown
around last year were not correct."

What were those numbers?
"More than 6500 residents of Libby and nearby areas in Lincoln
County have completed medical screening by federal medical teams.
''There will be over 600 new cases added to the 400 people in
town already diagnosed." Scientists conclude the hazard added to the
inhabitants of Libby run 4000% to 6000% greater than the general
population.

Commercial interests are always ready to deny science by its not being
100% accurate. I am sure that W.R. Grace would allow that perhaps 599
will be added and science need only admit its error and retract its
faulty conclusions as science now shows it seeks to damage the
reputation of the commercial interest and destroy its trade. (Duh!!!)

It should be noted that this was a breaking story not because of the
general tragedy of certain death, but more for the greater tragedy of
commercial interest covering up scientific evidence through
stonewalling and collusion with government agencies' passivity.

Insofar as the argument for cellular exposure and injury, recent study
has shown the penetration depth of fields into the skull. For
children, teens and small adults, this is considerable filling nearly
half the brain pan. Obviously any commercial interest that draws the
emitting source closer to the skull is going to condemn this as
"pseudo-biometry."

For the general readership:
There has been discussion of these fields expressed in power per square area. This can be nearly as hard to follow as the discussions couched in mV/M. In other words, what does this mean to me? Consider the ultimate everyday radiation exposure - the Sun. At the equator, at noon, on a cloudless day, on the surface of the earth, the Sun applies roughly 1KW per square meter (the average adult has two square meters of surface area). This can also be expressed as 100 mW/cM^2. Up here in "Rain City" I can at best expect only 30mW/cM^2 on a summer's day, and yet 15 minutes exposure is certain to burn me (your mileage may vary). As this exposure is not direct, but oblique (through my movement during exposure) it suggests some lower figure can produce this damage (still more than 10mW/cM^2 certainly). Note that it is not necessary for my entire body to be exposed to suffer the burn of 1 cM^2 patch of skin (my ears - say) as the frequency of exposure has wavelengths so short that damage is measured in fractions of this same cM. Radio waves on the other hand have much less energy than sunlight with wavelengths measured in Meters to several cM's. The mechanisms of excitation and damage for light do not produce similar damage for equal power at vastly lower frequencies. As such, the sunlight-damage metaphor is lacking, but it still serves a useful touch stone of relating these units of measure.

As 30K is about 5 miles, you should have no problem with a minimal system depending on the sensitivity of the receiver. I am wondering how you contend with the winds aloft that can reach 100Kts easily at these altitudes. A low mounted dipole or loop normally is a real cloud burner and should work well for your application. the over head pattern on a 1/4 wave vertical would not be to your advantage.

Source record: 174561

Working on communal TV systems I often find 75ohm coax that loses five or more times more signal than it should. The losses are always greater at higher frequencies. The problem usually arises when the cable is old, and sometimes I have been able to track a gradual increase in loss over a period of years. Sometimes the explanation is obvious – the cable has taken up large amounts of moisture via unsealed ends. But often there is no obvious moisture in the cable. I wonder if cable takes up moisture through the outer sheath, because sometimes the dielectric is slightly discoloured. Any thoughts, ideas, suggestions?

Source record: 174564

My fairly extensive experience from a NE QTH is that a 50ft dipole will beat
a full sized vertical with elevated radials about 90% of the time into
europe on 80m (I have both and A/B them often).

Many of the dx stations you readily hear on the low bands are running a kw,
and remember that you're 10dB down on their end if you're running 100watts.
Add QRN and european QRM into the mix, and they might not be able to pull
you out.

GL/73,

And we all shall scream for ice cream.

Someone perhaps well known in the U.K. said your knowledge was thin and tasteless unless quantified.

So, the U.S. Army found from careful measurements repeated over time to prove repeatability that a 1/2-wave dipole only 7 feet above good soil is 19 db better than a 15-foot tuned whip with a near perfect ground connection.

These tests were performed by transmissions between like antennas (the difference in transmission levels was 38 db for the two dipoles over two vertical whips) at 3 MHz via the F2 layer over a 75-mile path.

If the dipole were 20 db better than a whip, the power gain would be 100. 19 db is about 79 times the power from a 1/2-wave dipole over that obtained from the whip (in or out of the same field).

With dipoles on both path ends versus 15-foot whips on both ends, the power gain is 6310 times, approximately, (38 db).

Best regards, Richard Harrison, KB5WZI

>At 160 meters, two feet off the ground is such a small fraction of a wavelength
>that it would make virtually no difference.

A small move up away from earth does make a difference, but efficiency
will never be really high with only four radials until they are 1/4 wl
or more above earth. Even at 1/4 wl of height, the radials are still
coupling to the lossy dirt below the radials (even if at greatly
reduced coupling compared to wires near or in the dirt).

If you have a direct ground path to earth, and only a few elevated
radials, it actually hurts efficiency a measureable amount. That's
true even if the path is the shield of the coax. You always should
have a choke balun or other isolation on the coax at the feedpoint
when using a small elevated system.

>the ground. Please understand, when you have so many radials that the antenna
>does not "see" the actual earth, then leaving them on the ground is ok. It's
>only when you have just a few radials that elevating them up high would reduce
>ground losses. Something around ~120 radials qualifies as near-perfect.

Some actual 160 meter results here:

The actual point of equality, between elevated radials at 6-8 feet and
radials contacting the earth, was at about 15 -20 radials here at my
house. Once I had 25 radials or so, they could be laid on the ground
or elevated with no noticable change in FS.

4 elevated radials was about 4-6 dB less FS than 60 radials either
elevated or laid on the ground in all actual FS measurements I've
seen.

Once I get to about 40-60 radials, FS barely changes as I add more 1/4
wl long radials. On my omni-vertical, 100 two-hundred foot long
radials is only a fraction of a dB better than the same tower with
only 50 radials 100 feet long.

My 4-square for 160 meters has only about 50 radials per element.

A 1/4 wl or 3/8 wl long vertical with 50-60 radials or more always
ties and often beats a dipole at 300 feet on 160 meters in a direction
broadside to the dipole. Of course off the ends of the dipole, the
vertical smokes the dipole at any distance, time-of-day, or day.

A low dipole beats the vertical within 100-200 miles on skywave, but
almost never at any larger distance. W5TJ in Mississippi (300 miles
from me) is louder here with his 120 foot vertical with NO radials

than he is with a dipole at 100 feet. The same is true back from here to Frank (except my verticals have large ground systems so the difference is greater).

In contests, or in regular operation, the verticals work so well I have all but abandoned use of the high dipoles and a low dipole.

With a 4BTV, I'd either ground mount it in the clear with as many radials as long and straight as I could muster, or else roof or mast mount it. I'd still use a multitude of radials even if up in the air. Four for each band is NOT enough unless the antenna is near 1/4 wl above ground or higher.

It depends on what the cell-phone looked and smelled like, or who was
using it.

If Helen Hunt or even someone like Goldie Hawn was using the phone, it
could stay there for a year. If that icky fat girlfriend of Clinton's
(Monica) was using it, I'd want it gone every morning before I woke
up.

>am.
>
>Scott.

Scott,

Like many things in life, the real problem is with the female.

The male end of the UHF connector set is almost perfect. There is no
bump there.

At the female-end, a simple typical SO-239 has an impedance of 30 to
40 ohms. However, that "bump" is only 1/2 inch long, so it will NOT
caude a problem unless you have a lot of them spaced the wrong
distance apart at frequencies below 150 MHz or so.

Even at 450 MHz, the effect is often minor.

The pro's outweight the con's in my book, since a conventional good
quality UHF connector set will handle much higher line SWR and power
than a N connector. A regular UHF connector is much easier to assemble
also.

N connectors are fine below 1500 watts with low SWR, and constant
impedance connectors are needed for critical measurements or UHF and
higher work, but they are not needed below 200 MHz or so in almost any
application.

Barrel connectors are a slightly worse problem since the length is
longer. The general rule is if you keep the length of slight impedance
bumps below 1 electrical degree, they won't bother almost anything you
ever do.

That means on 160 meters you could have 1.5 FEET of total connector
"bump" area before before you could measure any difference. On six
meters, that would be only one connector....but remember this is the
WORSE situation where you could normally measure any change at all.

Doc's statement is pretty much in agreement with what I have seen.

To Europe, a 35 foot tall top-loaded vertical with 60 radials pretty much always tied a 100 foot high dipole for me at my last QTH.

Not so at closer diastances, and not every night at longer distances.

Most people, if they can have them, have both. Listening on the low end of 80, some of the best European and Asian signals come from verticals.

Reg wrote:
"Eureka! - throw up an inverted-L or a sloper. Get the best of both worlds."

The U.S. Army tried those antennas, too. With like antennas on both ends of the path, the inverted-L`s, with a 45-foot top and a 35-foot downlead, produced 2 db less than dipoles only 7 feet above the earth (at 3 MHz).

At 30 feet up, 1/2-wave dipoles produced 21 db more signal than at 7 feet up. A sloper from 30 feet up sloping down to 5 feet up (the sloper was also 1/2-wavelength long) produced 9 db less signal than the dipole up 30 feet at both ends.

If you install a 900-MHz dipole or colinear horizontally beneath the aircraft body postioned 1/4 to 3/8-WL below the conductors and control rods inside, I would think it might yield a wide pattern with a little gain toward the ground, while providing some cancellation above. I might try a mylar-film groundplane spaced behind the radiating element for increased surface area and better uniformity.

Also, woudn't it be easier to manage signal diversity at the tracking site (where weight and drag aren't issues) than to install a turnstyle on the aircraft?

Finaly, check the airborn receiver, transmitter, and camera in a deep-freeze before flying them! It get's wicked cold at FL350 and strange things happen!!

Yes, there are both 50 ohm and 75 ohm BNC connectors.
However, the main difference is not the diameter of the inner conductors
(essentially identical). It is the amount of dielectric which is
present. 50 ohm has more than 75 ohm.

Mechanically, 50 and 75 ohm connectors are totally 'inter-connectable'.
Also, electrically, I doubt if you will see any difference in amateur
use.

Also, the 'inner parts' of 50 ohm BNC and N connectors are essentially
identical. You can make an electrical connection between a male N and a
female BNC.

IMPORTANT NOTE #1: This is NOT true for 75 ohm N-connectors. The
diameters of the inner conductors of 75 ohm N-connectors are MUCH less
than for 50 ohms. You can NOT connect a male 75 ohm N to ANY BNC or N
female (the inner conductor simply does not make contact).

IMPORTANT NOTE #2: NEVER, NEVER connect a 50 ohm male N to a 75 ohm
female N. You will end up with a SERIOUSLY damaged female. If I had my
way, this would deserve capital punishment for a second offence!!!

Hi Nick,

Yes I realize the jest here. However, the radiation from any consumer
device is regulated by the FCC for non-interference (which almost
always means too much power radiated). This is not a slack issue and
the industry learned how concerned they were some 10-12 years ago at
ComDex when the FCC walked the aisles with emission measuring
equipment and immediately confiscated any noisy "toys." A cold
shivver went through the exhibition hall with the dismal prospect of
salesmens' demo machines being snapped up and hauled away.

I like your analogy, again consider the quality of life if you were to
survive being hit with the weight of that cow in "cow-chips" when one
chip at a time hits you every 10 seconds you were on the phone. ;-)
Sure, the risk is spread and life goes on (no one is dead over this).
This says nothing of the risk of mad cow disease (which may be the
reason you are being hit once every 10 seconds - a very mad cow who is
annoyed by the ringer).

Hehe, of course, I was on a rant, heh. And what about laptops? Many don't have much shielding. (Although mine has large sheets of aluminum and such underneath for heat disspiation/shielding.)

I was just exaggerating a bit...people like distorting things to make them sound bad. Yes, a cell phone could harm a person, if it had a transceiver in it that required it's own power generator.

I'll leave my odds of getting harmed from cell fones in that same arena that contains the probability that I may get hit by a flying moo cow. (Watch a tornado hit me in the middle of winter ;))

Hi Bill,

As a lineman for CATV company. My knowledge has been moisture enters through the connectors. Failure to use silicone, bi-seal tape, shink boots around ETE and amplifier housings. This corrodes the center conductor, whereby different freqs. are effected (skin effect etc.). This is for hardline and is the same for subscriber drops. In a subscriber drop once water has a chance to get in the braid it acts like a wick and can draw water like a pipe if it has been up long enough.
Bill losses will always be greater the higher the frequency that is being utilized.
If you want to keep water out, Always use a silicone based non-hardening compound. Coat lightly on the threads of gorund block, splitter etc., never ever put silicone on the inside of the fitting as this compound is somewhat of an insulator and you could effectively null all signals out, by getting some on the center conductor. Never ever use RTV since it hardens and you may one day need to get to the fitting.
Keep splices to a minimum the less the better. If you have to always use bi-seal material to cover the splice, at the least use electrical tape- I always found electrical tape just allows the water to be held in to corrode the splice but if you use a silicone compound on the threads of the barrel connector and on the fittings themselves it should work ok.
Bill I don't know what climate you have to work with or if you are working with hardline or RG-11 or 6 but if you have any more questions feel free to email. I just gave a few suggestions off the top of my head but I could give more specific answers if you give me a better idea of what you are working with in the way of equipment etc.

Regards,

I recently came across some information indicating that 50 and 75 ohm BNC connectors have the same pin sizes. The different impedance is effected by removing some dielectric around the center pin in the 75 ohm version rather than changing the pin diameter. So they'll mate without damage. I don't recall where I saw this, but think it was in some literature from a connector manufacturer, and it sounded like this is standard for BNCs. Is this true only for BNC and not for N connectors? Or do only some manufacturers do it this way?

It would be really interesting to see a plot of attenuation vs frequency over a fairly wide range, and one from a piece of new cable. This might give some clues as to whether the loss is due to corrosion of the conductors or contamination of the dielectric, and knowing that might help point to the mechanism.

Since the inner on those MHV connectors mates before the outer shield,
the punishment could indeed be capital.

Mine said "don't take this phone orally" Hmm....

Funny...the "warning" section says that it meets all federal guidelines, and not to export the phone (in my Moto's manual). It also says not to use it around blast sites as your phone could set off explosives...hrm...that worries me...not.

My Samsung SCH-2000 PCS fone's manual says...Hrm, the exact same thing....funny...

Scares me to death really...er...well...not really...

The pin diameter is the same, in the parallel-sided part, but the end tends to be more pointed in the 75 ohm plugs. This means that a perfectly assembled 75 ohm plug may not mate reliably with a 50 ohm socket. With typical off-center amateur assembly, there's no problem.

The MHV connector is an accident waiting to happen. Not only is it designed so that it can be forced into a BNC socket, but also the HV center pin mates before the grounding shield. The SHV connector is far safer because it cannot mate with anything else, both center pins are deeply recessed and the shield connects first.

This whole thread is comparing apples and oranges. At the low frequencies mentioned (3 MHz) a very low dipole will work fine for short distances during the daytime, since the signal travels essentially straight up and down. If you were ragchewing with your buddies on 75 meters within a 100-200 mile radius at high noon, a dipole seven feet off the ground would be great. Working 80 meter DX at night, however, the same antenna would be a total waste of time.

That's why there is no "best" antenna. Gotta be more specific as to use.

Hi Ian,

In the Navy, we used to call these suicide adapters. Another risk was
found at our RTTY patch panels that used phone plugs to carry the
juice in the loop. Which end to disconnect first?

Neither could hold a candle to the AC Mains to aligator clip leads we
called the KillsMeQuick.

After wracking my brain for a place to mount my new Diamond F22A 2m vertical, I designed an eave mount that worked out very well. If you have exposed rafters on your eave (pretty common here in San Diego), this might be a good alternative for you too. It is so much nicer than having to mount a push-up type mast, etc. The article is at http://www.eham.net/articles/1612

Bill Turner, W7TI wrote:
"At the low frequencies mentioned (3 MHz) a very low dipole will work fine for short distance during the daytime, since the signal travels essentially straight up and down."

Behold the radiation pattern of the dipole. It forms a doughnut around the wire. There are nulls off the ends of the wire. The pattern reflects at the surface of the earth, but except for cancellation of radiation towards the horizon, there is plenty of radiation over a wide range of elevation angles. It does well towards the zenith, at most antenna heights, but it also does well at much lower elevation angles. How low an angle depends on how high the antenna. Plenty of power can be radiated at a low enough angle to cover great distances in just one hop.

From the War Department`s "ELectrical Communication Systems Engineering":
"Figure 6-130 gives some quantitative comparisons for several types of antennas tested over a 75-mile course in southern Florida using sky-wave transmission at 3 mc. Data for this table were obtained by comparison of pairs of antennas on dfferent nights, (Note: NIGHTS) togeher with cross comparisons made in order to reduce data on all the antennas to a common basis."---
"Figure 6-130. Sky-wave transmission between like antennas, 75 miles, 3 megacycles, F2-layer."

These tests were night tests when attenuation at 3 MHz is lower than during the day. Propagation near and far is usually better during the night.

The point was made by Terman. Vertical antennas can radiate well towards the horizon. Horizontal antennas radiate well at angles other than towards the horizon, and radiate well at higher angles even when the antenna is low. The army proved Terman`s story with tests.

As I previously said, the world`s shortwave broadcasters would be using vertical antennas for distant targets if they were economical and effective by comparison with horizontal antennas. They rarely use vertical antennas for shortwave broadcasting.

Best regards, Richard Harrison, KB5WZI

Don:
Many of the larger hardware stores and industrial supply houses carry cable. If you live near the ocean I would recommend stainless steel cable although it is harder to find. You can buy crimp ferrels and make your own loops. You just insert the cable into them and smash them down with a hammer.

Good luck Dick K7RNZ

A key word there, I believe, is "economical". A good vertical with its attendant radial system could easily be more expensive than the usual horizontal dipole. Many hams believe that verticals are simple, take up little space and are desirable because they consist of only one element. When all the factors are accounted for, horizontal antennas are often less expensive and better performers than verticals, dollar for dollar.

One exception to this is AM broadcasting, where verticals are nearly universal. This is done for one reason: They want groundwave coverage, which horizontal polarization does very poorly.

Source record: 174503

The trouble with the horizontal vs vertical question, is there are too many extraneous variables,
especially with verticals. From my QTH in Silicon Valley, a full sized 80M dipole at 55 feet was
virtually interchangeable with a full size (1/4 wave) vertical (ground mounted) with 2 elevated 1/4 wave radials.
Running a KW, I couldn't even get a QRZ out of JA stations calling CQ contest. This QTH
is near a rock quarry, and probably has lousy ground conductivity. It is also hemmed in by mountains.

From my weekend QTH in the Sacramento river delta area, I also have a 1/4 wave vertical, but
I easily work JA's with 10 watts and even work 75 meter long path QSO's to Europe. The
difference is that the ground is high conductivity (15mS) and I have 360 radials 1 wavelength
long on this vertical. It is also out in the clear away from bldgs. So the answer is probably that
under ideal conditions the vertical is better, but under typical conditions, the dipole is as good or better.

I talked to the president of US tower recently, and asked him about tube towers, and he said
they will be happy to sell you a set of replacement cables assuming they can identify the model
of tower OK. He will even support Wilson and Tristao towers where possible. One thing though,
they can't give you any written documentation due to liability problems. Don't forget to check
your pulleys. They can help you with those too if they need replacement.

Considering I've seen everything from *oral* contraceptives to *nasal*
inhalents telling you not to put it in your eyes/ass/etc I'm not really
surprised by that...

> Funny...the "warning" section says that it meets all federal guidelines, and
> not to export the phone (in my Moto's manual). It also says not to use it
> around blast sites as your phone could set off explosives...hrm...that
> worries me...not.

This message (actually telling you to turn OFF your phone) is also
usually on a highway costruction sign when you go through blast zones.
Travelling (by car) on i40 in the mountains and up 75 through either
Kentucky or Tenn. (can't remember which at the moment) it was extremely
common when any road work was going on to see these signs.

I've never turned mine off going through these areas, and so far, so
good... I'd rather leave the phone on and take my chances than search
for the phone in my purse and crash while dealing with heavy
construction traffic and idiots who slow down to see what is going on.

It also depends on what you mean by "barrel" connectors. I have known both
the short uhf female to uhf female connectors and the uhf female-uhf
female bulkhead connectors described this way. (The bulkhead connectors
are about 2 inches long (5cm) whereas the others are about 3/4 of an inch
(2 cm) long. The bulkhead connectors have horrible effects even at VHF
frequencies and shouldn't ever be used for anything above 30 MHz in my
view.

The exchange with Reg about vertical versus horizontal antennas reminds me of the old story of bird collisions damaging the windscreens of British aircraft.

The British asked NASA about a rumored NASA chicken corpse cannon used to test windscreens.

It exists and the Brits are welcome to borrow the cannon.

The Brits reported back that the chicken corpse completely removed the windscreen, the pilot headrest, and penetrated the bulkhead behind the cockpit. Was some adjustment necessary?

NASA replied with three words: "Thaw the chicken."

Best regards, Richard Harrison, KB5WZI

Bob- I have some so-called 'barrel' connectors of 4 inches, and have seen longer. They are used to go through walls and window frames, as well as bulkheads. I wonder at your statement of 'horrible effects'. Have you had direct experience with them at ham frequencies such as 50 and 144 mHz? What level of attenuation did they cause?

This is not an idle question. I currently have a 3" barrel feeding the line for a tri-bander through a window frame, and am about to add one for a 6M yagi. It, and a 2M line now run through 1" PVC.

THe 'convert' program is excellent, and, when kept on the desktop as a shortcut, can be used easily. However, it does not (at least the version I have) give sizes for number designated stuff like '#10' and '6-32'. If Tomek needs these, he will have to go elsewhere.

The #10 wire size is 2.588mm diameter- the other scales are not used for copper wire, so dont count. The #6 machine screw size is nominally 0.138 inches in diameter, which is 3.505mm. the '-32' is threads per inch and is about .79 threads per mm.

Hope this helps- Bill-W4BSG

That confirms my experience with low dipoles and random wires over ~45
years. I certainly wouldn't argue that there is not a diminished low
angle component at low heights but it still can be very effective for

distance communications.

The danger is that an inadvertent transmission from your cell phone will set off the explosives. So you would rather take the chance of killing people than be bothered turning that thing off? What a fine human being.

Yes you can parallel two 50 Ohm coax cables to get an effective 25 Ohm cable. For one work project we needed a ten Ohm cable so we used five 50 Ohm cables in parallel. It worked great.

Nonsense.

Wave angle at long distances can be a few degrees, and the low horizontal has almost no radiation at that angle.

I have both low and high dipoles, and GOOD verticals with real ground systems.

Despite being in Georgia, where conductivity is generally low, 1/4 wl verticals are about equal to 5/8th wl high dipole for longer distances at best.

Compared to a 1/4 wl high dipole, the vertical often beats it by several "S" units.

If you doubt this, open a copy of ON4UN's low band DXing book and look at what people are using. Virtually ALL sucessful low-band DXers use verticals unless they can get a dipole WAY up in the air. You will hardly find a sucessful 160 DXer using a dipole for that reason. Even as close as a few hundred miles on 160, the vertical will whip a low dipole.

Should we ignore all warnings because YOU say so? The authorities
in the UK are asking parents NOT to buy their children cell
phones due to possible radiation/health effects.

Safer Calls, or Selling Fear?
by Elisa Batista

To the dismay of the cellular phone industry, a company recently
introduced a device that it says would shield the human body
from the "biological effects" from cell phones.

EMX Corporation, a developer of technology that mitigates the
effects of exposure to electromagnetic fields, unveiled this
week a microchip that -- inserted in a cell phone's battery --
protects the caller's body cells from the electromagnetic fields
emitted by the cell phone.

The introduction of this new product underscores the ongoing question
as to whether radiation emitted from cell phones is a health hazard.
The cellular phone industry -- backed by the opinions of researchers
who don't believe it's so -- maintains that no evidence has been
provided to conclude that cell phone use has deleterious effects.

Similar to the "scrambling of a television signal," the EMF
BioChip emits a random electrical impulse or "noise" to overpower
the electromagnetic signal emitted by the cell phone and reduce
the effect on the caller's body.

EMX Corporation won't go so far as to say unequivocally that signals
emitted by cell phones could harm the body, but it touts research from
European and North American universities backing its technology.

Researchers from Catholic University of America, University of
Western Ontario, Columbia University, Aalborg University in
Denmark and the University of Washington in Seattle found that
cell phone EMF signals "bring the cells of the brain or other

parts of the body ... into a state of stress or shock," according to EMX Corporation founder and CEO Dr. Thomas Magnussen.

"You could see cells changing its (sic) metabolism and release stress proteins, which is a protective mechanism," Dr. Magnussen said. "So the cells are truly bothered by this electromagnetic radiation from cell phones."

However, members of the cellular phone industry and other scientists are incredulous, saying the amount of radioactive frequency signals emitted by cell phones is too weak to have any effect on the body.

>jacket?
>
>Pete

Hi Pete,

I called Belden about that, because a popular ham-myth is that
non-contaminating cables slowly increase loss from chemicals leaching
out of the jacket.

After transferring me to several people, I reached a "real" engineer.
She said non-contaminating means the cable jacket is stabilized and
remains flexible and intact over a period of years.

She said as far as she has ever seen ALL loss is due to corrosion of
the conductors, unless the cable is physically damaged. She also said
all corrosion was due to external contaminants getting into the cable,
with water being a major problem. She said they don't put "nasty
chemicals" inside the cable since the chemicals would have the
greatest effect when the cable was actually being produced and
everything was hot.

I recently measured some 20 year old RG-17 that I bought surplus. The
ends were well sealed, and the cable was stored indoors. The loss
actually measures slightly below factory spec for that cable, despite
warnings from people that the cable would be "junk" because of it's
age.

Everything I've been able to see or learn from reliable sources seems
to indicate moisture ingress in improperly sealed cables is the major
problem.

I've made dozens of test transmissions over the years as I drive
through construction sites, and I've never been able to set off any
explosions! But I've heard that a cop in New Mexico had a stick of
dynamite in his pocket, and laid his dash-mounted RADAR gun in his lap
which then set the dynamite off.

I also leave my motor running while I fuel my car, so I can use my
cell phone. But I've heard of a cop in Arizona who exploded when he
aimed his dash-mouned RADAR at the gas nozzel he was using.

Have a nice Christmas!

I have heard many people talking about the amount of ground radials
they run with their 1/4 wave virticals, Butternuts in specific.

My question is, how do people go about making the connections of the
ground radials to the actual antenna's?

Is there a special coupler for the Butternut HF9VX or are people just
using a hose clamp or whatever kind of clamp they have lying around to
make the connection.

Any reponses would be useful

OK guys, now how about the difficult one: "Common 1 PVC couplings"?

Outside of the USA, we can look up #10 in tables, we can look up 6-32
and get to M4 as the closest equivalent (as Brian kindly did)... but
"Common 1" completely defeats us.

There is a serious point here, which the QST editors ought to have
picked up: the assumption that "everybody knows what these are".
You can't assume that any more, as I've found out from writing my
magazine column.

It isn't only an international issue, or one of metrication. Even in
your own country, there will be significant numbers of people who don't
know what that "Common something" component is - especially when the
reference is to some other non-electronic area... like plumbing.

Yes Roy, attenuation versus frequency over a wide frequency range, 50 kHz to 100 Mhz, is the ONLY way of separating copper from dielectric losses.

Plot the results on graph paper as attenuation versus attenuation divided by squareroot of frequency. Accurate measurements are needed. Power-out versus power-in using your so-called SWR meter or Bird wattmeter is a waste of time.

Comparisons with manufacturers' spec figures mean nothing until a cable can already be seen to be dropping to pieces. Comparison with a known good length offers greater reliability.

However, strange as it may seem, measurement of attenuation is the most insensitive method of looking for defects in cables. Copper oxide has hardly any electrical skin effect on copper. It just reduces the effective diameter of the conductor. Loss noticeably increases only when the braid is severely corroded and is about to fall apart.

Cutting 95% of the wires in the braid, even all at one point, has no measureable effect on attenuation of a long length.

Polyethylene is a very inert substance. Underground and undersea polyethylene insulated telephone cables laid in the 1940's and 50's are still as good as new except where chewed by rats.

Faults are 99% due to physical damage to the sheath and at the terminations. And of course, due to defective workmanship at joints.

The foregoing remarks do NOT apply to the RG-58 junk sold to amateurs which has aluminised cigarette paper purporting to be an outer conductor.

Mat,

A few years ago I had to fit an antenna system with Andrews Heliax feeders to some equipment we had constructed . I seem to recall a warning in the 'assembly instructions' for the N type fittings regarding use of silicon grease on the threads. I cannot now remember the details but I guess there must have been a sound reason behind this. The grease is ok for use inside the plug or socket but must presumably have some detrimental effect when it gets between two connectors.
Can someone check this out - and if I'm right perhaps somebody can explain the reasoning behind it. After all it seems sensible to spread the stuff everywhere to try and waterproof joints but perhaps it has an insulating effect also?

Ok, that explains why the dipole is winning. At that low height, you have the same problem I do. Not really enough radials to make the antenna really work well. At that height about 60 or so would be close to 4 at a 1/2 wl up. Too bad you can't raise the antenna up to the 1/4 wl height. It would really sing. I used a full sized 40 gp at 36 ft with 4 radials and compared to a dipole at 36 ft. To dx the GP always won. Usually 2-4 s units depending on the distance. If only 1500 miles away, about 2 s units. If 5000 miles away, about 4 s units.
"no particular db gain claimed". I'm fairly sure if you raised yours to that height it would do the same. Or you could add more radials, but I know how that can go...Not always easy. A dipole does work dx ok. I've worked lots on 75m, but I would prefer a good vertical anyday if dx was the goal. But it needs lots of radials close to the ground, or be elevated preferably a 1/4 wl or more up and then you can get by with 4 radials."and have near 120 radial on the ground performance". MK

I'm wondering if the need for gain effects that decision though. I'm not sure the latest and greatest in SW BC antennas, but I assume curtains, rhombics, etc, etc. Seems if they wanted to point to a certain area it may well be easier with the horizontal setups they use. Also as one pointed out, no radials required either. They would need quite an array of verticals to equal I would think. I've been thinking about something I've never tried. Which would be better to dx, a 3 el yagi horizontally mounted, or vertically mounted? Both at the same 1/2 wl height I might add. The noise reception might be a tad higher on the vertical yagi, but just as a hunch, I would wager the vertical yagi would slightly outdo the horizonatal yagi to far off dx. And the lower the freq the better the vertical yagi. Anyone ever tried this ? Am I all wet in this thinking? MK

Bullseye. This goes along with my thoughts about the elevated 80m GP one other poster is using. If he added the radials to bring it up to an equivilant of 60-120 or so on the ground, he would see the same good results. At 1/8 wl up , you will need appx 60 radials to equal 120 on the ground. At 1/4 wl up, you need about 10-15, at 1/2 wl up only 4 is needed for the same appx performance. MK

That's what I did with my HF9V. Ran 12 wires across the property, intersecting at the antenna. Cut them, stripped one inch, and slid the bare wire between a hose clamp and the ground section of the base of the antenna. Tightened the whole thing when I was done. I also buried an 8 foot copper-clad ground rod about 4 inches from the antenna and ran several wires between that and the antenna ground clamp. I want to change that connection to a single piece of something like 4 gauge wire, and use a separate clamp on the antenna. This will just make it appear a bit neater, IMHO.

BTW, I could not get 17m to tune no matter what I did. It really wants to resonate at about 20 MHz. Either I assembled the antenna wrong, or used the wrong coils in two spots. I also need to lower the antenna and adjust the 15, 10, and 6m bands. Other than that, the lower bands are working fine and within spec.

Not sure you should conclude so quickly that the dipole is winning because of an insufficient ground screen. My experience at this QTH is that 4-5 elevated 1/4 wave radials 10ft off the ground work quite well on 80M and 160M.

I suggest that the arrival angle on 80M from europe is quite a bit higher than you might imagine up here (Albany, NY) and that's why the dipole usually wins. FYI, both antennas in the clear with gently sloping downward terrain.

The original poster was in NJ, and asked specifically about working into EU on 80M from our neck of the woods.

I have a similar dipole NW/SE at 50ft and the vertical usually beats that one into the pacific on 80M, also indicating that the vertical with elevated radials is doing its job.

>severely corroded and is about to fall apart.

The problem isn't cutting the wires, the problem is when they corode
or oxidize at the overlays where the braid weaves in and out.

Skin effect forces the current near the inside of the braid, and every
time a braid wire exits the current tries to flow through the lossy
poor connection to the next weave that is the inside.

>Cutting 95% of the wires in the braid, even all at one
>point, has no measureable effect on attenuation of a long
>length.

Yes, but tarnishing the braid a slight amount, or removing the
pressure on the weaves greatly increases loss. Fresh braid from RG-8
cable has more loss than a solid #14 wire at 30 Mhz when the pressure
is removed, such as when the braid is used in a tank circuit as a
connection.

PA's will typically melt the braid of RG-8 cable when used as a tank
lead, while #14 wire in the same spot will run cool.

Hehe, lucky for me I don't live near any blast zones...and even if I did I wouldn't really care. I just find it funny, right up there with Verizon's CellGuard insurance...stating that phone damage due to war or nuclear incident does not count, LOL.

Everyone go get a CellGuard pamphlet and read the fine print ;) It's rather humorous.

It's the electrically detonated blasting caps that may be
sensitive to radio transmissions. A stick of dynamite,
without a blasting cap wouldn't go off. One of the main
features of dynamite, is it's safety. You could even toss a
stick into a fire without worry of an explosion.

There may be a remote chance of that, but according to what
I've read, there's never been a documented case of that
happening with a cell phone. Also bear in mind, that the
radar transmitter will be running more power than a cell
phone.

To the dismay of anyone who understands electronics, or EM radiation,
read on!

>EMX Corporation, a developer of technology that mitigates the
>effects of exposure to electromagnetic fields, unveiled this
>week a microchip that -- inserted in a cell phone's battery --
>protects the caller's body cells from the electromagnetic fields
>emitted by the cell phone.

The battery is only a direct current source powering the phone.
Radiation comes from a time-varying current. There is nothing a
microchip inserted near or in a cell phone's battery could do, except
turn all the power off like a switch.

>The introduction of this new product underscores the ongoing question
>as to whether radiation emitted from cell phones is a health hazard.
>The cellular phone industry -- backed by the opinions of researchers
>who don't believe it's so -- maintains that no evidence has been
>provided to conclude that cell phone use has deleterious effects.

The introduction of this product underscores the need to protect
people from companies that pray on people's undue fears. Anyone who
understands electronics would know right off this is a rip-off.

If it is indeed a real news story, the reporter should be fired. A
responsible reporter would never publish something so obviously false
and easy to check out, especially something that just rips people off
by playing on their ignorance about a subject.

>Similar to the "scrambling of a television signal," the EMF
>BioChip emits a random electrical impulse or "noise" to overpower
>the electromagnetic signal emitted by the cell phone and reduce
>the effect on the caller's body.

A TV "scrambling chip" doesn't reduce the emission of a signal at all.
Actually, scrambling can typically add more energy and almost never

can reduce it.

The TV "scrambling" also is done at video or radio frequencies, it can not be done at "the battery" or dc power source. Even an electronics layman would know that.

>EMX Corporation won't go so far as to say unequivocally that signals
>emitted by cell phones could harm the body, but it touts research from
>European and North American universities backing its technology.

I'll bet. If they released obvious bolognia about how their system works, they probably have no qualms about releasing other false information they dream up.

>Researchers from Catholic University of America, University of
>Western Ontario, Columbia University, Aalborg University in
>Denmark and the University of Washington in Seattle found that
>cell phone EMF signals "bring the cells of the brain or other
>parts of the body ... into a state of stress or shock," according
>to EMX Corporation founder and CEO Dr. Thomas Magnussen.

Dr. Magnussen, if he is responsible for the technical misinformation laced through this story, obviously can't be trusted to provide reliable technical information.

I've designed equipment used in research at medical facilities studying biohazards of electromagnics, including for Dr. Art Pilla at Mt Sinai school of medicine, and met with researchers all over the world in this field. To this date, despite years and years of research, there has never been a link between cell damage and non-ionizing EM radiation (radio waves or power line radiation) unless the energy levels are high enough to produce measureable cell heating.

As a matter of fact, this research has led to devices which actually are theraputic...promoting healing.

>"You could see cells changing its (sic) metabolism and release stress
>proteins, which is a protective mechanism," Dr. Magnussen said. "So
>the cells are truly bothered by this electromagnetic radiation from
>cell phones."

Again, if this fellow is responsible for the technical content of this article, he can't be trusted.

>However, members of the cellular phone industry and other scientists
>are incredulous, saying the amount of radioactive frequency signals

>**********
>This news clip is continued at:
>http://www.wired.com/news/technology/0,1282,40660,00.html

Now if you want to read a real news clip, read this one. It is from the SF Chronicle, and was even a blurb on national TV news. Since it doesn't support fear and paranoia, they only ran it once or twice on

national news. This is the study that kicked-off all this paranoia!

Here's the unedited text:

A Lawrence Berkeley National Laboratory researcher fabricated data in 1992 studies that were considered tantalizing evidence that electric and magnetic radiation could cause cancer, a federal watchdog agency has found.
The dangers of exposure to electromagnetic fields generated by power lines, home wiring and household appliances have been hotly debated. A recent congressional report found that evidence of a link is weak.
But the studies by Robert P. Liburdy, reported in scientific journals, were significant at the time because they purported to show the first plausible biological mechanism linking electromagnetic fields exposure to cancer and other diseases including childhood leukemia.
In a recently released report, the federal Office of Research Integrity said Liburdy committed ``scientific misconduct'' by ``intentionally falsifying and fabricating'' his data to support assertions of cellular effects from electric and magnetic fields.
Liburdy, 51, resigned his 15-year position in March after the lab yanked his funding and agreed in May with the federal Office of Research Integrity to retract three data graphs he used to back up his conclusions in two 1992 journal articles.
The Tiburon resident, who received $3.3 million in federal grants for the research, also agreed to a three-year ban on receiving federal funds.
Liburdy denies any wrongdoing and said he agreed to the sanctions imposed by the Office of Research Integrity only because he could not afford a lengthy legal battle. He insists that the overall conclusions of the articles remain valid and will not be withdrawn.
Liburdy's studies purported to link electric and magnetic radiation and calcium signaling, a process governing many important cellular functions, including turning genes on and off and cell division.
He published the results in two 1992 journal reports, the Annals of the New York Academy of Sciences and FEBS Letters -- a publication of the Federation of European Biochemical Societies. He also presented it at several medical conferences.
He also used the papers to advance a research proposal and to get federal funding.
Liburdy's findings prompted many more studies. Since 1992, at least 20 scientific papers have discussed the connection to calcium signaling but have failed to find a conclusive link, said Chris Portier, an associate director of the National Institute of Environmental Health Sciences.
Cases of scientific misconduct are rare. Lawrence Berkeley Lab officials said there have been only two or three charges of wrongdoing by its researchers in the past 10 years, but they were not proved.
The Office of Research Integrity, charged with protecting federal health research funds, reviews only 12 to 15 cases of scientific fraud a year, said Chris Pascal, the agency's director. But he said many cases probably go unreported because people are afraid of

repercussions.
Arthur Caplan, director of the Center for Bioethics at the University of Pennsylvania Health System, said that when fraud does take place, it is usually because of pressures on researchers to capture grants, publish papers and get tenure.
Most scientists realize that such allegations can be the death knell for a research career, and it is rare that a scientist gets caught in outright fraud, Caplan said. ``It is a field that depends on trust,'' he said.
Scientists caught engaging in misconduct have been barred from federal funds for up to 10 years and sometimes face civil suits if their sponsoring institutions are forced to pay back grant funds. That is not the case with the Liburdy investigation.
Lawrence Berkeley Lab undertook its investigation of Liburdy after an unidentified whistle-blower challenged his results in 1994. In July 1995, the lab concluded that Liburdy had deliberately falsified data. The lab alerted the Office of Research Integrity, an arm of the U.S. Department of Health and Human Services. The federal agency's own review, which lasted two years, showed that the deception went deeper, said Chris Pascal, the office's director.
Using Liburdy's raw data, the agency found that in one graph he had used only 7.1 percent of the data points from his experiment and discarded the rest that did not agree with his hypothesis that the electric and magnetic fields affected living cells.
``In contrast to the data shown in the figure, the full set of primary data does not show that exposure to low strength electromagnetic fields results in an inhibition or in a lower level of calcium ions in the cells,'' the Office of Research Integrity's analysis says.
The report also said he magnified the response in his data and fabricated data to cover up his original deception. ``The evidence demonstrates Liburdy knew his data manipulations were significant to the conclusions of the paper,'' the analysis says.
Liburdy, who disputed the allegations of wrongdoing in a letter to the journal Science, said this week that he graphed the data by accepted methods and that all he would do in recanting his figures would be to clarify his technical procedures that were not detailed in the reports.
``The scientific findings are not wrong. They criticized me for how I graphed the data,'' Liburdy said. ``It is a matter of scientific opinion. They are not talking about the data being invalid. They are talking about the interpretation of the data.''
Three independent scientists who evaluated the facts at Liburdy's request criticized him for not explaining his graphing procedures but determined that he did not engage in scientific misconduct. The scientific conclusions are valid, they said.
One of the scientists, Richard Nuccitelli, a professor of molecular and cellular biology at the University of California at Davis, this week called the controversy ``crazy.''
``In a sense, it really is splitting hairs,'' he said. ``If you take the definition very strictly, he was guilty of presenting misleading

data. But if you look at the overall result -- is this a valid conclusion or not -- it is.''
But he and the other two scientists did not see the entire collection of data, said Stephen Godek, an attorney with the Office of Research Integrity.
The agency's report states that Liburdy's actions ``were significant misrepresentations that were intentional and not due to honest error or judgments about the interpretation of the data.''
As part of the negotiations with Liburdy, federal investigators agreed not to force Liburdy to retract the articles in their entirety because ``any scientist who would read those papers would know that without the falsified figures, the conclusions are meaningless,'' Godek said.

And when they released that warning, they also said that
there was no proof of a problem, but it was better to be
safe than sorry. This is particularly applicable to
children, as they are often more sensitve than adults, to
harmful influences. Now, if we could get parents to do more
about keeping their kids away from tobacco smoke, household
chemicals etc.

Talk about a load of BS. How is this "device" supposed to
work, without interfering with the operation of the phone?
If it "scrambled" the signal, the phone would be useless for
making calls. Also, if it "emits a random electrical
impulse or "noise" to overpower the electromagnetic signal",
it would be generating more RF enery than the phone and as a
result cause even more of the presumed damage.

Quite so, but if it comes down to having a decent signal or
not, there may be no alternative.

As I mentioned in another reply, there may be no alternative
to providing coverage to an area. Also, I have seen some
cell or PCS antennas mounted on poles, not much bigger than
a light pole. And of course the light poles along major
roads tend to be taller than those on residential streets.
Many utilitities do rent space on their poles to whoever
will pay.

In addition, with the creative use of plastic or fibreglass,
it's entirely possible to hide an antenna within a pole.

Anyone who understands electronics will tell you that is ridiculous.

While people can have legitimate concerns about radiation hazards, they should be aware that there are plenty of charlatans, con artists, and kooks more than willing to mislead them and prey on their fears.

Three of us in the central Iowa area are using the CW-80's. Put it up in flat top configuration, at least 35' and you will have a nice performer with good match on 80-10. You will need a tuner on some bands (particularly 30m), but not on most. It is a good antenna, but not magic. It's basically an off-center-fed dipole that tends to present a good match across most of the bands 80-10. It is narrow on 80m, in the same sense that any standard dipole is.

It may have some common mode currents in the vertical coax section that may or may not enhance the antenna's performance.

In short, it works well, outperforms the so-called "ground independent, electrical half wave, radial-less" verticals by a substantial margin.

Keep it away from towers (the center vertical coax section) and minimize any 'droop" away from the feed. It can V a little, but not a lot.

I'm quite pleased with it as a multi-bander that is easy to match and makes contacts without difficulty. Just think of it as a multi-band dipole that's easy to feed. If that is what you are expecting, you will be quite pleased.

As I recall you can plug ladder line directly into the coax connector AS
LONG AS YOU ARE RUNNING IT ON BATTERY POWER ONLY!

Don't have it plugged into the AC adapater for this kind of measurement. I'm
just sure this is in the manual somewhere. I was surprised myself that you
could do it this way and have it work, but that is my recollection.

Just put one wire to the center connector of the so-239 and the other wire
(of the ladder line) to ground.

(Look in the manual to be sure...I don't think I hallucinated this, but
anything is possible during the month of Ramadan.)

I would the the angle still fairly low even from the east coast to EU. I see a good increase when using a vertical many times on stateside signals. The amount depending on how good the vertical is. 4-5 radials at 10 ft is just not enough to cut the ground losses at that height. Sure, the antenna works pretty well, but it's not up to it's peak efficiency by any stretch. I remember one guy in particular on this NG that tried the same exact thing on 80m. And elevated at appx 10 ft with 4 radials or so, and then decided to ground mount and lay out 60 radials. The 60 radial version proved to be much better. He found the elevated one fairly lousy. And I still contend it's because it's not high enough for that number of radials. Now if you were to mount the antenna at a 1/4 wl up with the same 4 radials you will have a smoking antenna. At 1/2 wl up even better, although from my experience on 40m with a full size GP , 1/4 wl up will work very well. You need 60 radials at 1/8 wl up to equal 120 on the ground. At 1/2 wl up, you only need 4. My estimate is at 1/4 wl up, 4 radials appx equal 60 on the ground. So it's doing fairly well at that height with 4. If you use a normal elevated ground plane, I think you need it a min of 1/4 wl up to really work to it's potential with a small amount of radials. My 40m full size GP made my dipole at the same height"1/4 wl up" look fairly pathetic at night at any distance over 1500 miles. And I would think this would hold true for any band lower than 40 too. Actually, the lower the freq, the

more pronounced the vertical advantage I think. MK

...authorities in the UK are asking parents NOT to buy their children cell phones due to possible radiation/health effects.

Here in the US, where popular culture breeds depression, alienation, and school violence among teens, at least one celluar company has proposed mounting PCS antennas on schools specifically to empower America's youth to "think warmer thoughts".

It's further reported that, had Al Gore won the Presidency, a USDE Federal mandate would have forced all US teenagers to carry cellphones provided at local community expense in order to "foster communication and facilitate the thinking of even warmer thoughts".

Thankfully, Bush prevailed, bi-partisanship rules the day, and in a rare moment of cooperation and reconciliation, it's reported the NEA and NRA have hammered out a plan permitting teachers to carry sidearms in the classroom to enforce discipline!

I have been using an htx-10 mobile rig as a base station for a little while now, and have been trying to find an antenna for my car.

I came across a "secret sam" "hidden antenna" for CB that was manufactured by gold-line.

It can be viewed here: http://www.crbbooks.com/catalog_2_item/hid.htm

I can't make out fromt he picture what this thing is.. Does anyone have any ideas? Would this work on my 10M rig?

Here's the description:
This unit turns your vehicle into a full-performance mobile CB antenna.
AM/SSB operation on all channels. Easy installation,
shipped with instructions, 18' cable, all wire,
connectors &
hardware needed. Won't interfere with AM/FM radio reception. Everything's inside the vehicle.

Isn't around 3MHz used for broadcasting in the tropics (too much QRN on
the 'medium wave'?).

I seem to recall reading (was it in the 'Wireless World', circa 1990?)
that Sri Lanka was using very low, horizontal dipoles in order to get
pretty solid coverage of the whole island. There was (of course) very
local coverage (up to a few miles from the TX), then a dead area, then a
reasonable signal out to about 300 miles. The principal was, of course,
propagation 'straight up - straight down', as described above.

I expect that there was deep fading on the odd occasion, but it did
enable most of the island to be covered by a single transmitter. I think
that the system was operated by the Rediffusion company.

I cut some 1/4 inch aluminum plate material 12 inches by 12 inches and cut a slot up the middle 1 1/2 inches wide and mounted a small aluminum angle on it 2 inches long with holes for a standard u clamp from radio shack to clamp the plate to the aluminum tubeing just below the insulator. All around the edge of this plate I have 10/24 stanless screws and double nuts. One of the nuts holds the screw to the plate and the other nut is for clamping down the wire radial. You can see a picture of it at
http://n4zou.homestead.com/files/butternut.htm

Mat,

A few years ago I had to fit an antenna system with Andrews Heliax feeders to some equipment we had constructed . I seem to recall a warning in the 'assembly instructions' for the N type fittings regarding use of silicon grease on the threads. I cannot now remember the details but I guess there must have been a sound reason behind this. The grease is ok for use inside the plug or socket but must presumably have some detrimental effect when it gets between two connectors.
Can someone check this out - and if I'm right perhaps somebody can explain the reasoning behind it. After all it seems sensible to spread the stuff everywhere to try and waterproof joints but perhaps it has an insulating effect also?

73, John, G8OZH

Hi John,

You are correct the silicone compound does have an insulating effect. That is why you do not want to get it on the center conductors or any thing that requires an electrical connection. I quite honestly do not know the exact specifics for the N type connectors but I would gather it to be the same. However someone may have the exact answer. I do know on Cable TV hardline connectors you need to coat the threads of the female connector which you are mating. Basically all mechanical connections should have silicon compound, but a little goes a long way so no need to trowl it on the connectors.

I hope this helps. I do not really post that much but usually take in all the good info I have received and quite honestly have received some great information.
I am by no means the guru on this subject but I do hope I have been of some help.

Regards,
Matt

4470. Re: Need Airborne Antenna help...

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-20 15:32:12 UTC

Message-ID: <3a40cf95.523701@news.harvard.net>
Source record: 174322

There is a lot I have not said here, because this started as a
discussion of antenna problems.......

The system as build has GPS, airspeed and altitude telemetry.
This data is sent over the audio portion of the video TX.

I have already talked to the FAA and started learning what will be
necessary wrt permits, permission etc... to fly in the airspace above
18K ft.

I plan to do a test flight of all the airborne radio etc..... on a
balloon. I've already built a chamber for low pressure testing out of
big PVC pipe, and an automotive vaccume tester.

I've done some low temperature testing with a styrofoam cooler
and Dry Ice.

Back to antennas....
How can I build a an accurate 90 deg phase delay line at 900Mhz
with minimal test equipment?
Anyone in the Boston , or southern New Hampshire area that has the
proper network test equipment and would be willing to halp me test
/setup the antennas and matching networks?

Mark Keith wrote:
"My 8 ft. mobile on my car outdoes my dipole at 36 feet on 40m at night at 1500 miles."

That might be expected from the characteristics of Mark`s antennas as shown in figures from the ARRL antenna book, if losses are ignored.

In my 14th edition, Fig. 12 shows F2-layer propagation requiring elevation angles from the horizon of 10 to 25 degrees to reach 1500 miles.

Mark`s 36 foot high dipole is barely more than 1/4-wave high at 40m. It thus does best straight up. Fig. 25 shows radiation from 1/4-wave high horizontal antennas. At 10 degrees, there is very little radiation, and at 25 degrees, radiation is several db down from the maximum aimed at the zenith. At 1500 miles and more, you are unlikely to rattle their cans with a dipole only 1/4-wave above ground.

Fig. 48 shows radiation from vertical antennas. It makes a half-doughnut lying on its sliced side and encircling the antenna for short antennas. At elevation angles of 10 to 25 degrees, radiation is almost the same as the maximum value aimed at the horizon.

Figures 27 and 28 show a need to get a horizontal antenna up between 1/2 and 5/8 wavelength, or more, to get the most radiation at angles suitable for F2 propagation at 1500 miles, or more.

Cecil, W6RCA, had a nice comparison of vertical and horizontal antennas on his web pages, if I recall correctly. Hopefully, he still shows that comparison there.

Best regards, Richard Harrison, KB5WZI

>dissipated in the tuner.

You say "almost all the energy will end up being dissipated in the tuner". That depends on where the tuner is located in the system. If you have the tuner installed directly at the base of the antenna with no coax at all, it will probably do ok, but if it is connected even a few feet away the loss in the coax will be quite large.

With the example above, the best way to match the antenna is the old fashioned way that's been done for 50 years or more: Cancel the 2000 ohms with a coil of that reactance and use an L network to match the .29 ohms to the 50 ohms of the line. Works great, is much cheaper than a tuner and you'll learn some interesting things about matching and resonating antennas. Perhaps the most interesting thing is that you don't even need part of the L network - the antenna itself can be detuned to provide the missing part. Details are in any ARRL handbook.

4476. Non-symmetrical radials

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-20 17:21:34 UTC
From: Pete Holden <peholden@home.com>
Message-ID: <yU506.57474$x6.25162629@news2.rdc2.tx.home.com>
Source record: 174325

I have a 20m, homebrew vertical, a ground plane, mounted on the peak of my roof. It is a bit over 16 feet tall with its base about 0.38 wavelengths above the ground. I have five radials radiating out from its base, each the length of the antenna. The worst SWR I get is 1.2:1 and the antenna seems to work just fine. I guess I should be satisfied.

But, due to the arrangement of my roof, the radials are radiating out over a partial circle (maybe 200 degrees). The open part (no radials) of the radial circle points northwest.

My question is, does this make my antenna somewhat directional? Is there any problem with not having the radials evenly divided?

Thanks, Pete KA0TZK

>

David your two cents is worth as much as anyone else's. But are your figures the result of numerous repeated accurate measurements, or something you read, from whatever source? I had an engineer friend (now SK) who wouldn't use a PL259 for ANYTHING. I didn't argue it with him, but I've used both 259's and N's extensively on the job, and have had far more operational problems with the N's-mostly those installed by someone besides me at some earlier time.
A properly installed PL259 (many people do a terrible job installing them, unfortunately) has done everything it was asked on all the gear I've been around up thru UHF with no problems. N's have been more troublesome and fragile, often after being in service for some time.
Of course the thread about 'too many of them in a feedline causing a high SWR' is a factor to keep in mind. One on each end of the feedline will be a more reliable installation than N's on each end, from what I've seen.
For sure RCA's are something less than most reliable, whatever their loss.

Dick

Pete,
Yes, your antenna radiates in a somewhat directional pattern. But!
The degree of directional pattern shift is so slight, it just isn't
worth worrying about. If the small difference in radiation pattern
shift that is present stops you from hearing a station, more than
likely,
you wouldn't have heard them anyway.
'Doc

Last week here in our town, the scare mongers prevailed on the school board to decline Qwest's proposal for a PCS tower built onto an increased height parking lot light standard at a local elementary school. In so doing, they turned their backs on maybe $400/month income and the promise of a high bandwidth internet connection (they're making do with dial up now.) I had explained to the principal about pattern nulls under vertical collinear antennas, etc, etc. I wish I could have attended the board meeting but had to be out of town on business. Oh well. I'd be happy to have the thing on my property.

Off topic (sort of): check me out on the 3830 list for the 10m contest. Roughly 1.6 million points. But I wasn't handicapped in the antenna department. There was a picture of my antenna in a recent QST article by Tom Schiller relating the FQ (fun quotient) to the antenna gain.

Yes, a little.

If you download the demo version of EZNEC from www.eznec.com and
model your antenna, you will see exactly what happens to the pattern.

==========
Download program SWR_FREQ

Takes only a few seconds.
Not zipped up.
Run immediately.

Enter feedline impedance equal to antenna input resistance
when at 1/2-wave resonance.

As frequency deviates from resonance the swr increases above
1 to 1. The program user sets the swr value to which the
bandwidth is to apply.

A folded dipole has slightly wider bandwidth for a given swr
but not as much as often claimed by those who have only
heard of the effect.

(A bit wary of a virtual tar-baby here...) OK, so is that ever an issue until the pair is mated? I never did disagree that the mated pair has a problem with respect to impedance, and I'm well aware of the impedance as a function of distance along a typical mated pair. But I'd for sure say it's a _system_ design problem, not the "fault" of the female half of the system. If there's blame to be laid, I'd lay it at the foot of the system designer; but the fact that UHF connectors are STILL in very common use after well over half a century says there must be something right about them: inexpensive, reasonably rugged, ... As with nearly everything, there are compromises in connectors. One size does not fit all. I suspect we're in good agreement on that.

And as I wrote before, IF the designer of a transmitter/transceiver and the designer of an antenna properly took the effects into account (as noted before, they are the ones that have control over the female ends that are part of their pieces of equipment), the performance of UHF connector systems at 440MHz can be just fine for ham applications, SO LONG AS the ham that uses them doesn't screw things up by putting a bunch of barrel connectors along the line. But a single line with connector at the transmitter and another connector at the antenna and nothing but low loss line between will be fine for most ham applications. Now if you think I use UHF connectors on my spectrum or network analyzers...

BTW, I had previously written something about "two 1-inch-long 25 ohm segments" potentially causing greater than 2:1 SWR at 450MHz. The example I ran that gave the 2+:1 SWR was with two half-inch-long segments, more like just a single mated pair at each of two locations along the line.

Cheers,
Tom

4490. Re: QUESTION: Can shortened radials be effective?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-20 20:48:51 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3A411B33.1B8334E9@eznec.com>
Source record: 174338

The analysis you cite is the basis for a widespread misconception about verticals and the comparative performance between verticals and dipoles. I was really saddened to see it repeated.

The problem is that loss CAN'T be ignored when dealing with vertical antennas. The pattern you see from a vertical will only vaguely resemble the half-donut pattern unless salt water surrounds the antenna for a distance of at least several wavelengths. If you mount your vertical over real ground, even with a radial system that has essentially zero ground loss, the pattern won't look much like the donut. The wonderful lower angle radiation is virtually gone, and the signal strength is much less than the perfect-ground case. The net result is that quarter wave high dipoles compare reasonably well with verticals even at fairly low angles. (The verticals do increasingly better at lower frequencies, very low angles, and regions with higher ground conductivity.) In contrast, ground loss hardly affects the signal from a horizontal antenna except at very high elevation angles.

You'd do yourself a favor by getting a later version of the Antenna Book. I believe it was the 15th Edition (which is about twice as thick as previous ones) that Jerry Hall completely re-edited and largely re-wrote. He got rid of a whole lot of mythology which had crept in over the years and replaced it with good information.

You might also consider downloading the free EZNEC demo program from http://eznec.com. It clearly shows the profound affect that ground conductivity has on the signal from vertical antennas, and makes it easy to directly compare the field strength between a vertical and a dipole at any height, at any elevation angle.

Hi Bill,

Obviously some "winning" relation to either cell phones or cancer (as
no link was provided, missed, nor responded to). I can see how cell
phones and "winning" (sp?) could be mutually beneficial (given the
off-topic divergence) but hardly as a boasting point.

Sorry don't know about such a program, but a used a standard program to
model my tape-antenna, inputting about 1/3 of its wideness as diameter.
I made a 3 el yagi with folded dipole as radiator and I'm quit satisfied of
its performance in fox-hunting. (i didn't made any measure of its gain or
F/B ratio or beam angle but just
resonance and impedance).
The impedance is 100 Ohms, matched with a lambda/4 75 Ohms TV cable.

Roy Lewallen wrote:
"The problem is that loss CAN`T be ignored when dealing with vertical antennas."

Alas, that is too true. Problem is that loss must be determined by the site and actual equipment and most often is unknown until measured.

The older edition of the Antenna Book agrees with many other texts in presentation of theoretical (lossless) patterns. I mentioned the ARRL book because I thought many would be able to look at the figures for themselves. I don`t have a newer ARRL book. It would have been informative to have the effects of loss included.

I`ve heard that someone is giving me a copy of the newest ARRL antenna book for Christmas. So, next time I post, I may not be so ignorant.

The elevation angle at whch a horizontal dipole begins to surpass a vertical in radiation depends on losses as Roy says. That is a good reason to use EZNEC which obviously takes into account the losses it`s told to use.

My intent in posting was to explain why Mark got better DX (1500 miles) with his vertical than with his 1/4-wave-high dipole. Mark`s mobile installation is apparently very good, because most I`ve seen would have difficulty in competition even with his too-low dipole.

The sufficiency of 1/4-wave height for horizontal antennas is something I hear repeated often. I believe this fallacy may be based upon obtaining a drivepoint impedance near 70 ohms. Too bad most of the radiation is nearly straight up from a horizontal antenna at this altitude. This altitude is good for near vertical incidence, which was what the army was after in the example I gave from the WW-2 handbook. No fallacy at all is involved if you want sky-wave coverage of a few hundred miles or less. The 1/4-wave high dipole may be the best antenna for you. For greater distance, it is helpful to bring the elevation angle of the radiation down by getting the altitude of the horizontal antenna up.

I`ve actually installed horizontal dipoles at offices and in oil camps around South America and seen how they worked. At low elevations, you get the near vertical incidence results as discussed in this thread. For DX, horizontal dipoles have to be raised nearly twice as high as the 1/4-wave-high vertical incidence antennas.

I could also tell of many events while trying to use HF SSB mobiles in the Land Rovers and trucks we had in South America. They had long whip antennas mounted atop fiberglass boxes containing the loading coils with

motorized tap switches. The results weren`t good. We did much better with VHF FM after discarding the SSB.

Best regards, Richard Harrison, KB5WZI

>
> Thanks, Pete KA0TZK

It may be somewhat directional, but probably not enough to make any significant difference. Despite every precaution, nobody's antenna pattern resembles that which is predicted by theory -- there are always factors which affect the pattern. Any problem with not having the radials evenly divided is not likely to have any noticable effect. If you were to notice a consistent lack of contacts from a given direction it might be worth looking into. The main factor which you have already indicated is that it "seems to work just fine" -- have fun. Antennas are funny people -- they fire the arrows into the air, but you cannot always predict where those arrows will land. 73 and gud DX

All,

Looking to replace an antenna. Because of several restrictions, I really need it to be a through the window mount. I would like to hear from any of you who have used any 2 band 2m/70cm antennas and which ones any of you would recommend. My previous vehicle used a RS ant that had adequate performance but I know there has to be much better antennas on the market.

Thanks
Mike

>from the galactic center ?

Over a period of six billion years, it's pretty high.

>What it the propability that a species generated in this process will
>develop nuclear bombs and fly to the moon?

Over a period of a million or so years - very high.

>The probability is low, but it happened anyway.

No. We have no idea what the probablilities are, because we have so little information. The sun is an ordinary type of main-sequence star - there are millions of them visible to us. How many of them have planets like ours? Nobody on this rock knows. Earth could be unique, or there could be millions just like it out there.

We do know that some other stars have planets. Maybe most of them do.

What's the probability that Earth is unique? I say much lower than anything you described.

Richard- If you read the enclosures, also, there was a post from Yuri on this thread. The thread had been going along mostly on topic, until Chip had to twit Yuri about his (Chips) unanswered challenge re the 10M SSB contest. Why he chose that thread, instead of just issueing a straight jibe at Yuri, the Lord only knows. Yuri had told him long ago that he (YUri) was not interested in playing with children during a serious contest.

Hope this helps- Bill-W4BSG

Ye...es...and it was that unfounded hubris (of Yuri's)that led me to challenge Yuri in the 10M contest--a challenge he did not take up, for the simple reason that he harbored doubts as to his ability to beat me with my tiny fractal antenna and low power. And, of course, the right set of operating skills, honed first some 30 years ago--long before Yuri even knew what a contest is..

Now we know why he backed off: it appears I came in second in the country. Do you think Yuri would have come in first? Looks like we will never know. But based on his operating style I very, very much doubt that he could do the number of Q's I did at LP. With my lil' fractal quad yagi:-)

John

Given the supports - trees, what ever

Install half square - also called a half
bobtail array.
feed in corner with coax of ladder line

has two in phase vertical sections
with maximum current and radiation
at the TOP !!! great antenna !
You will need some space
K3KY has nice web page on
bobtails and half bobtails.
Great dx antenna !!!

FINALLY a positive comment on the B&W! I have used them for years
both at home and professionally, and have had as good a luck with them
as with a random dipole and a tuner, without the bother of a tuner. I am
sure there are a few S units difference between it and a cut dipole, but
I like the antenna myself. :-)

It will. But a 40 meter spiral wound works poorly on 15 and 10. I'd say its because the impedance of the spiral wound section acts as a series RF choke on the bands that are very much higher in frequency than the band the antenna is designed for.

Convert that statement into engineeringese any way you wish.

Actually, with the aid of a little hindsight, it is 100% probable. :-)
We are viewing the universe from the center of that 100% probability
which may or may not affect our objectivity.

Dick, all my "engineeringese" is in digital logic and microcomputers.
Ham Radio and antennas are merely my hobby. When a mobile antenna is
used on a higher frequency than its intended frequency, it demonstrates
a relatively low capacitive reactance between the turns of the coil that
can result in an LC resonance with the inductive reactance. The result
is called self-resonance where most of the energy is exchanged between
the inductive reactance and capacitive reactance with massive I^2*R losses.

In general, mobile antennas radiate well near their resonant frequency and
below. In general, more inductance than is needed should not be used on
a mobile antenna. I've heard it is possible to get a screwdriver with a
large top hat to resonate on 10m as a 3/4WL antenna. I'll bet that
configuration is pretty lossy.

Source record: 174170

Thanks to Mark, Cecil, Ian, and Dick for reinforcing what I tried to say in my earlier posting. My, I had no idea what a nerve I was striking! <:}

I think that the original poster fell prey to the notion that a wire running from his shack equipment to a rod in the ground obviously had to be an r-f ground since that is what he intended it to be.

Sadly, even our simple little hamshack and antenna installations often are far more complex than we recognize or care to admit.

If any have taken offense at my comments, that is unfortunate, since my remarks were intended to be objective and technical, although I did bring in a personal note or two largely to suggest some credibility to my statements.

Anyone is free to organize their equipment anyway they please. If it works to their satisfaction, bless their hearts and more power to them.

But, let us all please think for a bit before publishing bold statements that simply do not hold up in the face of what has been known on this subject for the better part of 100 years.

It is a desirable goal for our station equipment to operate at zero r-f potential. It is not a necessary condition for effective and satisfactory operation. Above all, merely connecting a convenient length of wire from some piece of equipment to some sort of ground rod some distance away does not constitute the implementation of an "r-f ground." Nor is such an arrangement a fundamental, required element in any amateur station if proper antenna engineering has been done.

My screwdriver antenna operates that way with only a coil from the
feedpoint to ground. Detuning the antenna to provide a capacitive
driving point impedance does the trick. As Bill says, it was described
in the Handbook in the 50's.

I have a R8 that is less than 6 months old and I am having problems
witht he antenna also. It was working Great and then all of a sudden
its like having a dummy load on the end of the coax!

I checked the coax (Which is also new) and Its not shorted and gives
me a perfect SWR when I connect a dummy load out there on the end of
the coax. Cushcraft (After a bunch of phone tag) had me send them the
matching box back to them, they tested it and returned it saying its
fine. I used to get better than a 2 on every band with out my tuner
now I get over a 8 swr and I can receive better if I connect the coax
to my dogs collar!

I spend over 400$ on that antenna, its the LAST $$$$ Cushcraft will
ever get from me!

Worked great, Looks Great, Does not last
I can not afford almost 100$ a month for an antenna!

===============

Yes, the program displays data only up to an SWR = 3
bandwidth. I didn't think anyone would be interested beyond
that.

What's an algorithm ? ;o) Everything is an approximation.

The antenna is considered as a 1/2-wave resonant
transmission line (which it is) with an impedance Zo. It
has a Q (sharpness of resonance) factor as does any tuned
circuit. The damping resistance is the sum of the radiation
and wire loss resistances. L and C values are those
appropriate to a transmission line of impedance Zo.

The feedpoint impedance, Zin = Rin + jXin, is then
computed versus frequency. Eventually Zin is compared with
the feedline impedance to calculate SWR versus frequency.

The most simple approximation would be to consider the
antenna as a series tuned circuit consisting of L, C, Rwire
and Rradiation, where the resistances are the equivalent
lumped values. And it should not be forgotten radiation
resistance itself changes fairly rapidly with frequency.

However, knowledge of the bandwidth at the antenna feedpoint
is mainly of academic interest because the bandwidth at the
business end of the feeder, the tuner and the transmitter,
is modified by the feedline. In general, the bandwidth at
the transmitter is made more narrow by the feedline and a
tuner. The longer the line in terms of wavelengths the
smaller the bandwidth. Only when line loss is several dB or
more can the bandwidth at the transmitter be greater than
that at the antenna.

Another factor which makes antenna bandwidth only of
academic interest - antenna feedpoint impedance hardly ever
exactly matches the line impedance even at resonance. This
in itself narrows the bandwidth for a given SWR as can be

seen from the SWR_FREQ program.

THis is a pretty good example of what I call an unfair attack. By your own words, the antenna was working fine when you first used it, and had a sudden change to poor performance. Logic tells us that something changed in the hook-up at your location, and did so abruptly. The fault can be found, and probably with only simple equipment. Why blaim the R8 when it was delivered in working order?

You say you have checked the Coax, and CushCraft has checked the box. Why did you stop there, and blaim them? There is more to the system than that.It is apparent that something changed at your location- maybe a 'hit' or a loose connection?

just my slant on it. Bill-W4BSG

Those can do a good job. When I was running my GP on 40m, another guy here in town ran a bobtail. His was the fairly normal three legged variety, and fed at the center element at the base with a high voltage cap. He was the only local that could outdo me to VK land. MK

They work much better when resonant. What I would do is use a 20m stick
for 20m, and when you switch to 40m, add a 3 ft stinger whip to the top.
It will then work well on both bands, but you will have to get out to
switch. All hamsticks with very short stingers are fairly lousy
antennas. The longer the stinger on those the better. Can make a very
large difference in performance. A 20m stick and 3 ft stinger work very
well on 40m. Without the stinger , it will be the pits. MK

Cecil, W6RCA`s post contains his web page address. A few clicks will let you see how EZNEC compares a 40M vertical versus a 40M dipole at a height of 66 feet (1/2-wavelength).

Other good stuff can be found on Cecil`s pages, too.

Best regards, Richard Harrison, KB5WZI

It's no slouch...:) BTW, I was quite surprised myself when I first noticed this. It was about 2 AM one morning. I had driven over to a local choke and puke to eat breakfast one morning and was driving back home yakking to this guy I know in FLA. I got home and pulled in the driveway, and alerted him to stand by, as I was going in the house and getting on my dipole where I would have a "real" signal. Much to my surprise and dismay, when I got in the house on my dipole, I dropped strength a small amount. Maybe 5 db's worth or so. I tried it a few more times, and was repeated every time. Was no fluke.

I agree a 1/2 is better for dx than a 1/4 wl up. But still, you can work dx at the low heights ok. You just won't be setting the woods on fire. At that appx time, I had the usual 80/40 dipole with one coax feed at 36 ft. I was working a guy in Sydney, and we decided for kicks to try 80m. I was 100w, no amp. About 2 AM local time. I might have been maybe S 7-8 on 40m with the 1/4 wl high dipole. When we went to 80m, I was still quite Q5, and dropped a bit, but maybe only an S unit or two. And on 80m, the antenna was now at only 1/8 wl. "36ft". Still worked dx ok. Now on 160m, my dipole is at about 1/16 wl up. It is fairly lousy to dx, but I have still worked a bit on it. Mainly to the Caribbean areas. Have worked a couple of those islands out there, so it's still working at low angles to dx, although my inv L will eat it's lunch in that case. The low, low dipole works to dx, but sure nothing to write home about. It's pretty lousy at 1/16 wl up compared to the L at low angles.

>73
>Chip N1IR

"Perthaps" I will give you a hint to some "acheivement" that might point you in direction of researching the subject before you make stupid statements:

If you explained and provided some material that you based your above conclusion and statement on, then you may read the following:

In 1971 CQ WPX Contest results (Feb 72) CQ Magazine had my color picture on the cover (first time contester on the cover)?. What were you honing?
Going further back -
Go check the CQ Magazine with 1965 CQ WW CW results, you would see picture of two operators on the first page of results, one of them called "Jurco" in the

stripe T-shirt (Yurko, was OK3BU), who is now known as Yuri, K3BU. By then I had years of contesting behind me and was awarded honorary title "Master of Sport" bestowed on exceptional sportsmen like Emil Zatopek, etc. Yes, ham radio was considered technical sport in Czechoslovakia. I have medal and a certificate (and pictures in the press) to prove it.

Now you got another egg in your face, go away, shape up and come back when you are pronounced fit by professionals in medical and legal areas.

Thank you,
hope it helps and have a nice day (or fuggetaboutit)
have a Happy Chanukah and don't confuse it with Christmas
like you did with Passover for "Easter breakfast"

... -.-

Yurko, oK3BU
Master of Sport

PS
I will not bother suing you for libel, defamation of character, antisemitic (antichristian) remarks, damage to my professional career, resigning from IBM, accusing me of running illegal copies of CT, calling Quad a Yagi, ad nauseam, ad nauseam....
By now you should realize that you should not tangle with me, every time you do, you look like bigger fool!

Sorry NG, I got provoked (again), trying to use plain unscientwific language in hope of getting the message through.
Back to Fruck delete key.

Unfortunately, if the coax was developing problems, it would become more lossy and SWR readings would be entirely useless. You need to measure the power being delivered to the far end of the coax cable to make this determination. You can make a fairly decent microwave dummy load with several hundred feet of lossy cable.

Pete

You are not alone. I used a B&W 370-15 antenna (T2FD type) for a number of years

with great success. The balun was 12:1 and the resistor was 600 ohms. I've been
on
the air since 1958, but moving around in the Navy made ideal antenna
installations
difficult. The B&W was an easy alternative. Yes, in the final analysis it was
down
somewhat from a dipole, but I worked everything I wanted including lots of DX.
B&W have always produced quality product and I thought their 370-15 was one of
them.

Mark keith wrote:
"What freq were they on, and the distances used?"

We had several frequencies in the 3 to 6 MHz range. We needed several due to broadcasters which would pop up or drift onto a channel we were using at times. We made no effort to adjust to ionospheric variations as we had no low, medium, and high frequency assignments.

Our main use was short-range communications, 40 or 50 miles. Usually it was base to mobile (including vessels at Tierra del Fuego) and these were usually within VHF range. We sometimes needed to communicate much farther, but we gave that up when we went to VHF FM.

Our SSB operators would be switched to the wrong channel and miss vital messages. Other times, the "speech clarifier" seemed to mystify the SSB operator. The RCA SSB equipment was a mess, too. Even at freezing temperatures, the plastic coil forms melted in the radios. In the Chaco Jungle, you can imagine the temperature problems.

So, Motorola FM proved quite a relief, even though propagation was almost limited to as far as the eye could see. I did talk to an oil-field supply house in west Texas from a Motorola Handie Talkie on one occasion, however. This was on 33 MHz. Of course we arranged relays and other strategies to alleviate the limited range problems. The operators could use the FM with few problems. We put up tall towers for our antennas, but these had to withstand monstrous winds at Tierra del Fuego.
I`m no civil erngineer, but we had a supply of line-pipe and wire rope, and I had steel handbooks. We also had excellent shops and welders. So, I designed the towers, made the antennas, and we put them up. I expect they are still standing and being used after 40 years.
Argentina "repatriated" the oilfield we found and developed, so I suppose YPF is the group now using the Motorola stuff or its replacements.

Best regards, Richard Harrison, KB5WZI

George, W5YR wrote:
Above all, merely connecting a convenient length of wire from some piece of equipment to some sort of ground rod does not constitute the implementation of an "r-f ground".

Very true. Wire has inductance and resistance.

2nd story shacks remind me of KTRH, 740KHz, a 50KW Houston station. The transmitter is located at Cedar Bayou on Galveston Bay. The site floods, so the transmitter is placed high above earth to keep dry during the floods. They have a 2nd story shack.

I used to visit the site. They had no loose r-f in the plant, burning fingers or anything else. RF grounding was the standard 120 barely buried radials from each of the four towers. This was connected with the plant via the coax lines to the power-divider/phasing cabinet. All of the plant grounds, including the r-f cabinets were connected to the a-c service entrance ground as required by the National Electrical Code. Ground loops were no problem.

The station gets out well. I listened to Dan Rather give a blow by blow account of Hurricane Carla roaring through Houston on my little hand held Hitachi transistor radio in Tierra del Fuego, I believe that`s about 9000 miles away, with scarsely any fading. KTRH does have a north-south directional array.

In olden times, many broadcasters located their plants atop high downtown buildings. I once worked for KXYZ which had an old Western Electric transmitter atop the Gulf Building in downtown Houston. Some FM and some AM broadcasters still locate plants atop tall buildings. RF grounding and isolation must avoid producing inhabited hot spots throughout the building, and they usually do. It should be no big deal.

The point is to use a balanced r-f connection to the load, or to use the feedline ground as the r-f connection to the antenna system ground. The r-f ground is needed at the unbalanced antenna. It is connected to your transmitter via the coax. You should do the same with your mobile installation. You ground the coax shield very well to the car body at the antenna. Bolting the radio case to the car body also, usually causes no problem. O.K. you use a mag-mount and have no connection to the car body at the antenna. Not so good.

Best regards, Richard Harrison, KB5WZI

Source record: 174191

The resonant Q of a 1/2-wave dipole, considered as a series resonant circuit, is itself a very slowly changing logarithmic function of the slenderness-ratio = antenna length/diameter.

If B is the bandwidth between the 1 dB points then -

For a 160m dipole with 18 gauge wire, Q is roughly 17 and B = 55 KHz.

For a 10 meter dipole with 10 gauge wire, Q is roughly 11 and B = 1.3 MHz

For a 2 meter dipole with 1" diameter tubes, Q is roughly 5 and B = 14 MHz

So nobody, I hope, needs to readjust the tuner between 144 and 146 MHz.

->
->Yes, the program displays data only up to an SWR = 3
->bandwidth. I didn't think anyone would be interested beyond
->that.

No, that's not the way I see the program working. I see some fractional bandwidth edges, not VSWR limit edges. I'll work it again later to see if it really is a VSWR limit or %bandwidth limit.

That's pretty high. But he didn't say the planet described was this one.

>We are viewing the universe from the center of that 100% probability
>which may or may not affect our objectivity.

Exactly. And our vision is extremely limited. We also see the universe as it was, not how it is.

We have no idea how common planets like this one are. We do know that millions of stars like our sun exist.

For all we know, the evolution of intelligent life could be as common as gravity.

It's bad, very bad. I've been designing industrial machinery for almost five decades and I thought I had every piece of common hardware dimensional data on the planet. I have nothing on the dimensions of PVC pipe fittings. I finally went to a local plumbing components emporium and put the calipers to a one inch PVC pipe coupling, the answer is 1.630-1.635 inches outside diameter, very close to 1 5/8 inches. 41.3 mm for coil form purposes.
>
The whole scene is outrageous.
>
About twenty years ago I found myself in Normandy working in an electromechanical laboratory gathering test data for a technical paper I was was writing. One of the young French EEs was grousing loudly about us retarded Yanks and our inches, no silly inches in France, etc. So in wanders another young engineer, more of a mechanical type. I pointed to an overhead pipe which carried cooling water to the (French designed/built) equipment we were working with, "Alain, what is the size of that pipe?" "Du and a half inch". Young nationalist sparky stalked off in a snit.
>
A few years later I was managing a small machine building facility in Toronto when Ottowa declared that Canada was metric and the use of inches almost became a criminal act. In order to encourage the use of metrics Ottowa offered to take in the precision inch measuring instruments then in use in machine shops such as micrometers, calipers, scales, etc. and pay for the metric equivalents. That offer set off a stampede of heroic proportions. The Japanese toolmakers sent in regiments of their sales staff as every skilled mechanical tradesman, inspector and metrology lab in Canada headed for the Japanese precision tool catalogs. Everybody traded their old (in many cases useless junk) inch instruments in for shiny new metric equivalent instruments and Ottowa picked up the whole bloody huge bill. Virtually all of that new instrumentation was dual-calibrated inches/mm and everybody continued to use inches as usual.
>
I've been wondering ever since what Ottowa ever did with the carloads upon carloads of old tools they bought.
>
For my own part I don't care a whit if we use inches, millimeters, angstroms

or furlongs, they're all just dull numbers and none of them are "rational".
I'm tired of the unending conversion pushups.

The biggest problem with balanced lines (vs coax) is that you need to manually tune up the antenna system for each QSY - particularly between bands. Many of the new radios have internal automatic tuners, but I don't think most of them have balanced output - (I use 25+ year old tube equipment that needs a lot of manual tuning, so I know what a pain this can be.)

I am looking for a source for a comparison of various tri-band beam antennas.

Help appreciated. 73, Don W6QEY

Where is the answer to this crap?

>>>> And, of course, the right set of operating skills, honed
>>>>first some 30 years ago--long before Yuri even knew what a contest is..
>>>>

Maybe you will understand this:
You are frucked up, get help you idiot. You can't even read, or carry on correspondence.
Maybe 1965 precedes your crap, or maybe 1958 even more?

You lost any shred of credibility or respect you were so badly craving for.

You failed as antenna designer, ... and now as contester. What else you wanna be? You are already idiot, moron, etc. Congratulations!!

Keep it up jerk!

Thanks Richard,
I have some stories to tell about those days, we organized the network and kept the world informed about the truth. I was very fortunate to get out, literally they missed me by hours, got on the plane to Paris. Other's were not so fortunate. They still sentenced me to 5 years, but by then I was calling CQ contest as VE3BMV.
God Bless Canada, US and don't let the dummycrats to establish socialist hell here.

Don- Ward Silver, N0AX, and Steve Morris, K7LXC did a study and reported at Dayton. They put it out, through Champion Radio Products, as "HF Tribander Performance". THey only tested nine antennas, and not everyone aggrees with them, but there are few comparative reports out there, and it has data you can evaluate for yourself.

Champion usually has adds in QST, etc. or you could use the CBA for either of them.

One of them was my dear friend OK1ZQ, Vasek, who managed to transmit form the attic of the ministry of interior, building that Russians took first. He kept QSO with UN rep. minister Hajek in NYC for about 3 days, without food, barricaded on the top of the building. He suffered greatly afterwards. Prosecuted, stripped of license, thrown from lousy job to lousier. He was holder of world record in CQ WW CW on 40m, with windom and 200W. Great CW op. Hams in Prague used trolley wires for antenna, Russians were going nuts, trying to triangulate the signals, they were everywhere!

Hi Yuri,

I follow Canadian politics (and mine) by watching "Royal Canadian Air
Farce." My buddy AA7UJ does a lot of business in Canada and his
assessment of the political spectrum there is that your right wing
falls somewhat to the left of Franklin Roosevelt's New Deal program.
;-)

WELL..... I am also glad to see that someone else like the folded dipole. I have run one for a few years and get great reports on it. It will cretainly take the power on HF, with a low SWR. Naturally it is not great at 160 m, but if you are limited on space. it is the way to go.

I have the 1.8-30, copper.

Put me down as a satified user.

Re: Line snagging in trees:

We've used a couple of techniques to minimize the difficulty with lines snagging in the trees. One is to use a pulley. The line goes over the tree and attaches to the eye of the block. Through the pulley is a loop of line that connects to the antenna, so it can be raised and lowered like a flag without danger of losing the end.

An improvement on this technique is to use aircraft type stainless steel cable. The pulley is still used, but the run over the tree is stainless cable, so it doesn't wear out for a long, long, long time. The line in the pully can be changed periodically, carefully.

Good Luck!

Don't let the negative comments unduly influence you Mike. There is
no question that the thru-the-glass antenna is a compromise compared
to a hard-wired antenna, but you can still get reasonable performance
from a good (Larsen) antenna. I have had one on my Jeep for 7 years,
and have never been sorry I didn't put on another antenna. I can
regularly hit repeaters out 60 to 100 miles with 50 watts. If that
isn't good enough for you, then you might have to look into something
else. Hey, an 11-element beam mounted on a pipe through the roof
would work a lot better. :-)

>Keep it up jerk!
>

What else would you like to discuss?I have some thoughts below.

>bada BUm1
>

Lots of people operated contests back then, but few knew what a 'contest is',
just as 'dx is'.

In 1965 getting onto the cover of CQ was no big deal.(At that period in the
magazine almost all the subscribers did(:-)--that's a joke)) Nor was

contesting. The only decent activity was on CW. And even that was modest by present standards.

The era of modern contesting was the result of the practical technical application of tranceivers and the outmoding of AM. That really didn't kick in earnestly til about 1969-70 with the wider use and acceptance of cheaper Drake; National; Swan; Galaxy; and Heath transceivers (among others).

In other words, it was, as you say, not much of a 'sport' until then. And operating in 1965 hardly "honed" one's skills. Unless you think listening to rx noise is a skill!

Again, I said I would beat you (in the 10M contest) and you still have the hubris to call yourself a "Master". Well, sir, give us your thoughts on my 10M contest performance. How would you rate it; how would you have done better; what evidence do you have for that assertion?

BTW,I remind you that your predilection for libel will get you into legal issues. So concentrate on the talent and technical issues, and not attacks.

Finally, what is your status in the US? You mention that you were about to be jailed in Czechsolovakia and then escaped to Canada. Frankly, I see no evidence that this was a political asylum, but your further info would be helpful. Are you a Canadian citizen with residence in the US? There seems to be some ambigiuity regarding this in public records. At least the one's we've found to date.

Kindly clarify, off line if you wish.

Cordially,

NC

The traps could be the problem here...I've had them blow up on Cushcraft antennas before when they get wet with even low power. Is the SWR the same on all bands? If it's not, take the traps apart and look for burned insulators, corroded connections, moisture or insect nests. I would also check for corrosion where the mast sections slide into each other. Clean those areas with a wire brush, and coat with "NoAlox" before reassembling. If it's the same on all bands, it's the coax connectors, or the tuning-box connections.

This thread is about the LACK of Support From Cushcraft, With a antenna that is less than 6 months old I received the same fine customer service that many other Hams have claimed here.

I want to thank the person with the idea of a watt meter at teh antenna end of the coax into a dummy load, I had not thought of that and it sounds like a good idea.

I was told by Tech Support at Cushcraft the the ONLY thing that can go wrong with the R8 Vertical is the Black box (Matching network). The antenna is Bran new so it has not coroded yet, I checked all coils with at least a Volt Ohm meter and they have a connection.

The antenna is in my pole barn awating the weather and time that will allow me to play with it some more. Here in Michigan we have had over 2 feet of snow in the last week. I spend more time with the snow blower than I do with my Wife!

Could I have another problem, I am sure I could, I do not pretend to be an expert on antennas and feedline. So I spend the money and purchased an antenna from experts. I will say there could be some information on there website about trouble shooting antennas. There is nothing that I have found. The simple trick of the watt meter at the antennas end of the coax into a dummy load. In fact I am already working on purchasing 100 feet of New coax to run out the door and just use to test and compart to eliminate the coax from the problem.

And about the antenna working when it was "Out Of The Box" Fine but if I buy a car and it has a warrantee I expect it to work throughout the Warrantee period and beyond.

Again just to clarify this thread was about the lack of customer support at Cushcraft, Them supplier me Customer, They are suppost to help me....

73's & Have a Great Christmas

Dick,

I have been a Ham since I was 14 so I know the limitations I am working in. Even the RS I previously had would hit repeaters 50+ miles out on 70 watts. As previously stated, I am stuck by restrictions that I have no control over. I would love to mount a 1/2 wave on the roof but I can't. Simple... I need to limit the mount to a through the window.

I have had other hams tell me a home made 20 meter antenna I once had "sucked". Meanwhile, I was talking to McMurdo Station on 50 watts when they couldn't with 1K. I take it in stride. A masters in systems engineering helps (g)

Thanks
Mike

Dick,

That one's easy. In aircraft, they run the ground lead
through a CMOS inverter. Turns the ground lead into
an antenna! And, if they want to save the cost of the
inverter, they simply fly upside down!

On another point:
For the ham shack in your home, I agree that an RF
ground should not be needed except as others have
noted (eg end fed wire). What has NOT been mentioned
is the National Electrical Code (NEC) requirement that, if
you drive an 8' ground rod for your antenna, you must
bond it to the house wiring grounding electrode system,
using some fairly heavy wire (#6 or bigger, depending
upon your service size). That is specified in NEC article
250 - 50, and receives little mention in ham radio
publications that talk about ground rods. The bonding
has nothing to do with RF ground - it is for safety.

Mike -

Get the Larsen 2-meter/440 glass mount and it will serve you just
fine. I was just pulling your leg about the beam. There are so many
hams bad-mouthing the glass-mounts I have to inject a little humor in
the discussion now and then. Just be sure you don't mount the base on
any metallic tinting or built-in metal shading like my Jeep has.

Actually not, at least not here, Curt. I can tune my wire antennas for say 40 meter cw and then operate from 7000 to 7150 with the internal tuner in the IC-756PRO or the Kachina taking up the slack. Changing bands merely takes a few seconds to set up some different numbers on the MFJ 989C tuner.

I use balanced lines to my wire antennas and then transition to coax via W2DU bead baluns into about 13 ft for RG-231 into the shack. From that point, everything is in coax. The heavy-duty external tuner takes most of the punishment in handling major impedance conversions which means that the internal tuner(s) are not at any risk in handling the small impedance changes due to QSYing within a band. I operate mostly QRP but never more than 100 watts into the antenna system.

> Thx, Bill

Calling the GAP Titan a "compromise" antenna would be very kind. For the sake of the group I will hold back my true impressions. The antenna that it was replacing was a bent up 40m dipole fed with ladder line and a tuner at the the radio. The bent dipole was better than the Titan on most bands. My other antenna was a cloud burner and consisted of an SGC auto tuner with approx. 40ft of random wire mostly horizontal about 20ft above a few ground radials and it out performed the titan (small case on purpose) on DX and local on every band. Even local 10m vertical polarized stuff was better with the SGC and a horizontal wire. The titan had a great match on every band, but so do my dummy loads. I have participated in many A/B tests of trap verticals (GAP, Cushcraft R7, Hy-gain) and a multi-band dipole on 40& 80m at distances from a few mi to about 1200 and the dipole has always won.
Happy antenna hunting!

You know, I have to admit that in just a few weeks of reading this
newsgroup, I have learned at least one profound lesson from you. I
never before fully appreciated the term "dipshit".

You are very much the consummate dipshit, and certainly have taken
dipshittery to new lows.

Before you send me any more unsolicited emails telling me not to send
you emails, which I never have and probably never will, consider that
they go immediately to the Dipshit bin, and are automatically
flushed.

A ham I know asked me if that stuff would work on two meters and I told
him,
"Sure, but I wouldn't bet on how much RF you'll get out the far end of
it". He was using something over 100 feet to his antenna. So he stuck a
wattmeter out at the far end, at the antenna, and it was delivering 5
watts out of the 45 he was putting inyo the coax from the rig.

Evidently it's pretty accurate, given that you can't understand the difference between opinion (accurate tho it may be) and malicious libel.

Tell you what Dipshit-(Jim has that right on)- Your should be sentenced to be booted out over Czechoslovokia in 1958 to fend for yourself. You couldn't begin to cut the mustard.

The same thing happens here below 40 meters. I speak for above 40...because I have no verticals up there since Yagi's are so easy to install.

Look at a sampling of antennas used by sucessful low-band operators, such as ON4UN's book. If a low dipole was so good, you'd see a lot of them used instead of the dominance of verticals.

>The sufficiency of 1/4-wave height for horizontal antennas is something >I hear repeated often. I believe this fallacy may be based upon >obtaining a drivepoint impedance near 70 ohms.

More than likely it is because people compare a vertical with a poor ground system (like four elevated radials) against their low dipole, and the low dipole wins.

You can certainly work DX on a low dipole on the lower bands, but it is my experience that a low dipole is rarely close to a vertical with a **good** ground. Most others who have compared both a good vertical and a low dipole agree.

There isn't any "dirt" in the world that is high enough conductivity
to not require radials.

Look at conductivity charts, and compare the conductivity of the best
soils to saltwater, and then compare the conductivity of salt water to
copper.

It's a delusion to think because your soil is 30-40 mS/m instead of
5-10 mS/m you suddenly have no loss!

Yep, I wouldn't think that would be too good at the 50-60 mile range. Little too far for reliable ground wave, and too close for a decent sky wave, and even if the sky wave was open "up-down" the antenna type is lousy for that use. I'd give it about a 50% workabilty ratio. I think I'd use point to point VHF with yagi's or something along that line. The hf would be great for longer distances though. 200-300 miles should do fine on 6 mhz in the daytime. About like my normal 40m daytime mobile setup. 40m a great daytime regional band. Usually anyway. MK

>Thx, Bill

Hi Bill,

You might search out the ARRL review where they compared a Gap to a
trap vertical with a real ground system.

On the higher bands, a Gap is OK. On the lower bands, it is a very
poor antenna. While you can make contacts, a low dipole would be MUCH
better on the lower bands for DX than a Gap.

I had a Gap antenna given to me several years ago. My 35 foot
top-loaded vertical with 60 radials was several S units louder than
the Gap at any distance, and 1500 watts would totally zap the matching
stub.

I now use the aluminun for a homebrew antenna.

Buy a Butternut, or any other trap vertical, and install a good radial
system..or a dipole fed with ladder line and a tuner. You'll be better
off.

>
>Well this can also cause cold solider contact in most cases.

We used that method in production of panel meters and never got cold joints. When soldering a delicate device, we would lay the device on a wet sponge while applying heat with only the joint area clear of the sponge.

The main thing that causes a cold joint (assuming it was heated enough and clean) is moving the joint while it is cooling, not how fast you remove heat after the solder flows. This isn't concrete!

How fast you cool the joint has nothing to do with joint quality as long you don't disturb the solder while it is hardening.

A little info:

http://www.qsl.net/aa3rl/titan.html

Do a search at:

http://wmod.dejanews.com/home_ps.shtml

Entering keywords " gap titan" results in ~200 relative posts, in which
resides a great deal of "magic" based hyperbole and enough rf theory based
common sense to debunk most of the fiction, if you care to look for it.

Many good technical posts among ~1000 older posts are not available, at the
moment.

>
>Just my 2 cents...sk

Not true at all David. That is a popular but totally false "hamlore".

The loss in a UHF connector is immeasureable on conventional meters,
and that's true almost no matter how it is installed. The exception
would be if the connector was open or shorted.

One thing that will help you sort out rumor from fact is looking at
the numbers. Let's consider the .5 dB loss you quoted. That's almost
10% power loss.

If I ran 1500 watts through one of "your" PL-259's, it would dissipate
150 watts of heat.

Now let's consider how hot a 150 watt lightbulb gets, even though it
has dozens of times more surface area than the 259! Try this test, run
1500 watts through the connector and immediately grab it with you hand
after removing power. Now do that with a 150 watt lamp.

Let's try to not propagate such utter nonsense as .25 to .5 dB loss to
people trying to lean. At HF, the N connector is actually lossier than
a UHF connector. That's why a N connector will be unreliable at 5kW,
and a good UHF connector won't even get warm.

The exception are junk connectors like those from Radio Shack, which
fail at about a kilowatt or so.

>say it's a _system_ design problem, not the "fault" of the female half
>of the system.

It's almost ALWAYS the female's fault, even when discussing UHF
connectors. Look at the design.

The females have to fit around the male, and so the OD of the gripping
contact is larger than it should be for 50 ohms. The male is perfect
right up to the pin, and that pin is totally enclosed in the female.

Even a male-to-male adaptor has a much smaller bump than a female-to-
female.

My point isn't to disagree about impedance-critical cases when the UHF
is not a good idea, but to dispell these nonsense rumors that N
connector are from Heaven and UHF connectors from hell.

The fact is, if the connector is in a communications system below 150
MHz or so, no one would even be able to tell the difference in
performance.

In communications systems below 100 MHz, the N connector is a more a
sign of anal-retentiveness in the person picking the connector than
wisdom.

Then let me continue with this.You have taken some delight in turning black into white...

Yuri has admitted that he was ARRESTED and about to be put in PRISON for 5 years until he ESCAPED from Czechoslovakia. Your assumption is that he was some sort of freedom fighter. I make no such assumption. I asked him what his arrest and prison sentence was for; notice he does not respond.

Frankly it appears to me that Yuri has a problem with authority--whether it be an authority on a subject or one which holds society together.

That is why I asked and await said clarification.Again, Yuri admits to escaping from a 5 YEAR PRISON SENTENCE.

That's pretty incredible. The question is: for what?

> 73 Tom

Thats fer sure. I have near those numbers here, and I still have the same problems everyone else does. Maybe to a slightly lesser degree, but they are still there. I need radials just like everyone else if I want to put out a halfway decent signal. You will notice the BC stations in this area still use 120 radials, good ground or not. MK

Jerrold--

Do you really want Dr. Browne to see this??

Nowhere in Yuri's comments does he say or impute the interpretation you made. I asked for further info and he won't provide it.

Again--based on HIS comments-- I would speculate that Yuri has a problem with authority of any kind.

No answer yet!
He is not revealing his intelligence gathering methods or sources. Now he got me into hot water and fired from KGB. I was terminated because I could not extract this information from Dipshitz (pssst, it is his cover name) and now they want to hire him. They never seen such a skilled individual (or multiple personality person) and KGB Major Fokoff will be contacting him soon.
I hope you are happy that you have ruined my professional career, my reputation, got me fired and taken bread away from my children.
Oh, oh! I hear Janet Reno's jack booted INS swat team knocking on my door. Looks like he told them about my immigrant status. I won't give up as easy as Elian. I will turn my TX on and paralyze their guns with EMP (those 8877s are good for something). They will be afraid to come after me, because of the FCC RF safety regulations, and they will not risk their lives for Janet. They will "know" that I would self destruct from the RF. If you guys don't hear from me, then you know what happened. On the other hand, if I can outsmart them like I did with reds, look for another something..BU.
See what have you done Dipshitz? Thanks a lot! I hope you can live with it!

Have a nice day!

Your status in the US is unclear. But there are pro's at work finding out more.

BTW, shouldn't there be a 'no power' category for SB220's that are unconnected and in storage? I can put my NCL-2000 in that category too!

And they are for sale (since I don't use them)

NCL-2000 $ 600
SB-220 $600

These haven't been on the air for a while so you'll have to do some clean up/possible repair. For these prices that's the caveat. U Pay Shipping.

Look- Dipshit- you can't even read with comprehension- just where did he say he was arrested? He said he got out just before the round-ups, and was only sentenced- in absentia, after he was out of the country.

You are so bent on blasting Yuri that you wouldn't know the truth if it hit you in the face.

You DO need help from a mental health professional.- As to being an 'authority'- as you implied- think again- the number of people that believe that is small, and getting smaller every day.

Hope this helps.

>Come on, now. Understand it? Of course I understand it.

If you understand it, then why did you give incorrect advice and
present it as a fact...instead of saying "I think" or "I guess"? Being
authoritative works better when you are right.

>Did I know
>specifically, cell phones are polled? --No I hadn't thought about it,
>but it makes sense, and I certainly understand it. That detail of how
>phones are tracked is irrelevant to the general discussion of exposure
>safety.

Anyone with any experience with RF would deduce they MUST do somthing
other than having an inert device laying on the seat. Anyone who knows
anything about exposure, or who has looked at it seriously, would know
how often the EM field was on.

>> To me, that indictates you give specific advice without understanding
>> how the system works, making your advice unreliable. I have a parrot
>> in the other room. One is enough.
>
>From my viewpoint, I've basically been responding to closed-minded
>statements from both extremes. It is ok to be skeptical. While the present
>US standard is believed to be safe, it did not come down from Mt. Olympus,
>and should not be defended as unalterable dogma.

The standards did come from more than 20 years of accumulated testing
in controlled environments. Despite all this testing, and researchers
standing to gain money and GREAT fame if they suceed in establishing a
link, the only agreement to this date between RF exposure and cell
damage is cooking.

Every single study that showed any link to cancer has been either
outright falsified (probably to gain status and money for the
scientist) or had very serious errors that show the reasearcher didn't
have a clue what he was doing. A prime example of fraud is the study
from California I quoted, and a prime example of unvarnished stupidity
is the study that (someone else pointed out) compared power lines to

Lukemia.

The damage is from heating, it is NOT accumulated damage if levels are kept below those that raise the cell's temperature. It is easy to quantify heating effects, and with a margin for tolerances added the results are 100% reliable.

The Chicken-Littles of the world may not like that...but that is the way it is.

>A few posts back you asked for a reference to the "so-called Russian
>standard", which I then provided.

So?

>Now you complain when I point out that
>the FDA is studying the effects of non-ionizing radiation (when only the
>paranoid would even consider such a thing) and cite a reference.
>-- I can't win, can I? :-)

I complained because you gave advice that is contrary to how the system actually works. Anyone who professes to understand the problem should also understand how the system works. Otherwise, it's just unreliable babbling.

For an example, look at the person who posted the nonsense about a microchip that cancels radiation. That person obviously hasn't the faintest idea about EM fields and how they work, otherwise they would never have quoted such absolute (and obvious) nonsense.

Like I said, I have a parrot in the other room. I never rely on his advice, because he just repeats things he doesn't understand. I love my bird, and certainly admire his good qualities, but he is unreliable for technical advice.

Cheers!
Tom

Any pressure contact joint can cause less than perfect linear
operation. That's true no matter what the materials are.

The level of that problem is insignificant in coaxial lines compared
to the loss problem.

Because it's none of your business. But I would wager to say it was for
being anti communist or something along those lines. "IE: refusing to
suck up to a bunch of !@#holes." I have a neighbor across the street
from Poland who did the same thing. He was a runner in Poland. When he
escaped, he ran out of Poland . Literally. He ran for his life. But a
tight ass sheltered little wanker from Boston wouldn't understand
something like that I guess.

I wonder why.

Serious questions :-

By how many dB would signal strength decrease if the number
of radials was reduced to 60 ?

Or if the number of radials was reduced to the point where
signal strength fell by 3 dB, how many radials would
remain ?

Estimates will suffice.

Mark Keith wrote:
"Yep, I wouldn`t think that would be too good at the 50-60 mile range.
(3 to 6 MHz)

Mark`s experience is the same as mine. We had many vehicular installations. These used vertical antennas as a practical matter. Vertical antennas have a null in their overhead pattern. So, short-haul ionospheric propagation is poor.

VHF`s advantage in line-of-sight communications is in its improved signal-to-noise ratio. Normal lack of ionospheric interference plus terrestrial blockage and loss lets you extend coverage. Antenna efficiency is usually much better too. As Mark pointed out, yagis and other high-gain arrays become practical, too.

We did continue using h-f for long-haul. For communication between oil camps and offices which involved hops of several hundred miles we had better equipment than the defective RCA SSB stuff. We had Collins 30K5 transmitters and 51-J receivers. No SSB, just AM, and with dipoles up as high as we could get them, usually 60 or 70 feet, we did just fine. Our frequencies were in the 3-6 MHz range, in competition with South American broadcasters which seemed to come and go at will. I also put a rhombic on Tierrra del Fuego to communicate with the public correspondence station near Buenos Aires. We had to use their frequency assignments. For that, we had a Hallicrafters HT-20, Glenn McCarthy had abandoned in Bolivia, and an Eddystone receiver I picked up at Radio Boliche ("Barato y Chi-Chi) in Buenos Aires. This was rock-solid. The Argentine Post office had a war-surplus BC-610 working with a dipole just down the road from our rhombic. No comparison at Radio Pacheco, the Argentine public correspondence station outside Buenos Aires. We knocked their ears off whenever we hit the air with our humble HT-20.

Best regards, Richard Harrison, KB5WZI

Probably the best answer to these questions is in the Brown, Lewis, and Epstein's 1937 paper. With their (undocumented but probably reasonably typical) ground conditions at 3 MHz, reduction from 113 to 60 0.4 free-space-wavelength radials resulted in a field strength decrease of about 0.4 dB for a 90 degree high radiator, and 0.7 dB for a 45 degree high radiator. To effect a 3 dB decrease required reducing the number of radials to 2 for a 90 degree high radiator and between 2 and 15 for a 45 degree high radiator. (For a 45 degree high radiator, 2 radials resulted in a reduction of 5.3 dB and 15 in a reduction of 2.0 dB.) All these are from Fig. 30 of the paper.

Some of the broadcasting professionals can correct me if I'm wrong, but I believe that a dB or two represents a noticeable (and costly) reduction in coverage area. It's also important for a broadcast station to maintain its coverage over seasonal and longer term changes in ground conductivity, hence the admitted overkill. But amateurs have different goals and requirements than broadcasters.

Roy Lewallen, W7EL

Nothing at all, if the n length of the radials was 1/4 wl.

The reason the FCC suggests 120 radials is they want to have headroom
in case some radials are damaged or the system deteriorates over time.

A second issue is stability when weather changes in directional arrays
A very tiny change is FS can result in a large change in null depth
since all elements may not change the same with soil moisture changes.

>Or if the number of radials was reduced to the point where
>signal strength fell by 3 dB, how many radials would
>remain ?

That information is well documented for all to see. Look at the RCA
study. While the results may vary from system to system, it will give
you a good general idea.

My own situation on 160 tracks fairly well with that study.

No BC station manager in his "right mind" would want to give up one
dB, let alone three.

4626. K3BU Prison Sentence

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-22 16:31:47 UTC
From: fractenna@aol.com
Message-ID: <20001222113147.21269.00005633@ng-co1.aol.com>
Source record: 174124

Yuri, K3BU has made the assertion that he was escaping a 5year prison sentence when he left Europe.

I asked him what the offense was and he refused to elaborate.

Several people here are making the ASSUMPTION that this was some political issue, but Yuri is either incapable or unwilling to verify that.

Here are the facts:

1) based on his responses, K3BU has real issues with authority figures. For example: in the last day has managed to attack President Clinton; Vice President Gore; Attorney General Janet Reno; various European groups, and me. For the latter, I presume this is because I represent an authority on a technical subject of interest to this NG;

2) I am not politician, and I am not a public figure.

3) Yuri has used, and continues to use, malicious libel and attack me.

If Yuri would like to elaborate rather than make personal attcks, this may be useful in understanding his position. Frankly, his responses strike me as childish, irrational, disjointed, and not of high moral character or integrity. That is my impression, and I would be happy to afford him the opportunity to clarify his statements and have me put these impressions to rest.

Sincerely,

Nathan Cohen Ph.D.

I rode my Uncle Sam's great grey yachts as a field engineer in a previous life. One had a surface search radar that had extremely poor range. Turned out that some swab had replaced a section of waveguide with a 2x4 halfway up the mast. As luck'd have it the SWR and all looked ok .....

Hmmm,

First you whine that you are abused by the use of your name/
call in the subject line of a newsgroup thread, and then you start
an abusive newsgroup thread with someone else's call in
this *public* forum.

First you whine that all you want is for the discussion of you to
stop, and then you *initiate* a new thread guaranteed to draw
more attention to you in this *public* forum.

First you claim to not be a public figure, and then you continue
to expose yourself to ridicule by posting drivel in a *public* forum.

First you claim (repeatedly) to be starting legal actions against
multiple individuals, and then you fail to follow through on
even one of these (public) threats to sue.

First you post that your attorney has advised you to not respond
to postings, and then you proceed to respond *in the same
message*!

First you claim that your attorney (real or imagined) has advised
you that someone has illegally wiretapped you, and then you say
"never mind" and "let it drop".

First you had a small group of sycophants filing in support of
you from the "fractenna" entity (most notably "Phil"), and
recently even they don't file in support of your rants.

Frankly, your behavior strikes me as "childish, irrational, disjointed,
and not of high moral character or integrity." That is my impression,
and I would be happy to afford you the opportunity to clarify your
statements.

Reg wrote:
"By how many dB would signal strength decrease if the number of radials was reduced to 60?"

Need to know the soil characteristics and frequency.

Ed Laport wrote the "Antenna" section of Keith Henney`s "Radio Engineering Handbook". Ed says to choose a site with good ground conductivity at least out to 1/2-wavelength from the antenna and down to the depth of wave penetration.

For details Laport says to refer to his RCA colleagues, R.F. Lewis and J. Epstein in: "Ground Systems as a Factor in Antenna Efficiency", Proc. IRE, 25-753, June 1937.
I believe these gentlemen along with G.H. Brown, also of RCA, "wrote the book" on radial ground systems.

Ed says 120 radials barely buried as needed for protection and 1/2-wavelength long make a nearly perfect ground. 95% to 98% efficiency may be expected of the ground connection.

Ed advises against compromise but says it is better to compromise the length of the radials than to compromise the number. I`ve read elsewhere that to use the wire saved in length by increasing the number of radials involves nearly no compromise at all.

Experiments have shown that at distances greater than about 1/3-wavelength from the base of a tower, ground losses are almost independent of tower height. So the radials are installed to improve ground conductivity close to the tower base. Often, a ground screen, or about 240 radials about 10 to 15 degrees long are layed right at the base of a tower, in addition, 120 of these radials are extended out to 90 degrees (1/4-wavelength) to complete the ground system.

In the U.S., the FCC requires AM broadcasters to use a system of radials at least 1/4 wavelength long and to use no fewer than 90, and says that there should be as many as praticable. FCC suggests 120 radials spaced every 3 degrees (equally spaced) and extending 0.35-0.4 wavelength from the tower. FCC also suggests a square ground screen 24 or 48 feet on a side. When a less than an "optimum" ground system is used, a complete field-intensity survey shall be conducted to establish that the field intensity meets minimum requirements. My recollection is that the stations I`ve worked in all had 120 radials from each tower, 90-degrees in length, and had a copper ground screen around and under each tower. That surely complied with FCC rules at the times they were constructed so as to avoid any special proof that the stations met the minimum field

strength requirements.

Best regards, Richard Harrison, KB5WZI

I have a 1/4WL 40m vertical with 8 radials. I have never heard a
signal on the vertical that is stronger than the same signal is
on my one wavelength 40m dipole at 40ft. I keep trying to find
that stronger signal on the vertical but so far it has eluded me.

Hi Jim,

Let's look at the record (in response to a posting of mine):
>I was very fortunate to get out, literally
>they missed me by hours, got on the plane to Paris. Other's were not so
>fortunate. They still sentenced me to 5 years, but by then I was calling CQ
>contest as VE3BMV.
has been rendered into
>> Yuri, K3BU has made the assertion that he was escaping a 5year prison sentence
>> when he left Europe.
as an obvious manipulation of the statement above. As there is no
other source of information than Yuri, these extraneous "facts" are an
invention. Let's consider on the face of it that the original
statement, although not specific, does include enough circumstantial
evidence to reveal that to have been operating as a Canadian ham
suggests that a license must've been obtained and in a timely manner
(how fast did the Canadian bureaucracies grant it?) FOLLOWING the
described event.

When my Dad served in Korea, he was a medic at a Korean POW camp
called Koje-Do. This place was so dangerous that the communist
internees managed to capture the camp commander and hold him hostage.
That is, until General "Bull" Boatner took over and cracked down. My
Dad's duties were inside that compound - unarmed - attending to the
sick and wounded. Several times, during riots he had to scale the
first perimeter fence (the guards would not shoot at any of his

pursuers until they followed him over that first fence).

The pressure in that camp was due to communist insurgents that volunteered (to their bosses) to be captured and interred in Koje-Do so they could serve as party leaders to the prisoners. They managed the riots and escape attempts and made sure that any escapee had a story to take back.

One evening my Dad discovered he was the subject of one such story when listening to Radio Peking announce his name being added to the list of War Criminals. As Dad was one of the few who was known by name within the compound (by those he was tending to), he became an automatic target to satisfy the commissar's quota of propaganda goals.

It is a shame that so many Americans are brain dead to the methods and practices of the commies that they support their agenda in the name of justice. I wouldn't doubt that these were the same sensitive souls and patriots that spit on me in uniform during 'Nam. The gulf that separates their ideals from their actions is immense.

Hi Cecil,

That may be so, but it doesn't respond to the question until you add
more radials and report the presence/absence of change. The question
directly above is searching for the quality of change or improvement
if you were to add more. The probable response would be no change or
a barely perceptible change (and this is the reason why he doesn't
remember the results - they weren't meaningful).

I suspect that if I doubled the number of radials from 8 to 16, my
vertical would outperform my one-WL dipole under certain conditions
but would it be worth the effort?

It follows from Cohen's arguments.

The communist regime in Czechoslovakia held that society together.

The nazis held the Reich together. The Jews and other "victims" of the
nazis had trouble with authority, so they were punished.

Is that right? The irony of the timing of Cohen's remarks is uncanny.

Those Macabees, why they just had a problem with Roman authority...and
their oil supply.

Roy Lewallen wrote:
"It`s also important for a broadcast station to maintain its coverage over seasonal and longer term changes in ground conductivity, hence the admitted overkill."

True, and that should be expanded to include short-term changes in conductivity. For example, a station by the sea might have its conductivity rise and fall with the tides. Or, a station in the desert might have its conductivity quickly rise after a sudden downpour were it not for "overkill" ground systems which made conductivity under the antenna good, come what may.

There is a regulatory problem, too. You don`t need 120 radials if they are always submerged under the sea. But, in the desert, more than 120 radials might be worth the cost.

The FCC allows variances from the rules, but the proof that performance is up to requirements is a burden upon the applicant.

The rules are reasonable because regulation must be in a sense a "one size fits all", except for the specials, operation. If every case was a special, regulation would be too costly. We already know what happens with no regulation. We attempt to get by with the least regulation possible, while providing enough control to avoid chaos.

Best regards, Richard Harrison, KB5WZI

Try asking on "rec.radio.amateur.equipment." That's where modification questions belong.

I don't have an answer for you. Most of the old equipment simply wasn't designed to go into the 1620-1710 range that was recently added to the AM broadcast band in the U.S.

If it has a synthesized local oscillator - can't say.
If it has a good old-fashioned free-running circuit - probably pretty easy. Over 30 years ago, I modified a radio to cover 160m (goes up to 2MHz). Still have it!

If it IS a free-running circuit, drop me a personal e-mail, and I'll give you the info.

Ian.

Jim,

How to you tune the antenna? Do you have a motor on the vacuum cap, or
do you have some preset positions for each band?

We didn't try that combo. It might work. The helical wound whips seem to act like a choke away from resonance.

We tried a couple of combinations, and were expecting the 40 meter model to be useable with a tuner on 80-20 at least. Was not effective at all. I would expect a higher Q antenna like a 40M bug-catcher to work fairly well on 80 with a good end-fed autotuner, does anyone do that?

> > Here is another idea. Change the top section of the screwdriver to a

The tube of screen is about as effective as a pretty big top-hat, and is easy to construct. I modelled it but haven't tried building it. The air resistance of either top-hat or wire tube may be an issue on top of the screwdriver coil, especially when cranked out to 75m.

Not so.

Yuri has asserted that he was to be JAILED for 5 years. Notice he never said why; it is only crass assumptions and speculations that ascribe this to 'freedom fighters'.He never, ever, said this.

I asked a Czaech friend of mine, who escape with his family during the 68 invasion. He knew quite a few hams and his father was an engineer then. What he said was very curious--.

"This Yuri fellow has a Russian name. Did he defect?"

I also asked a Russian co-worker. He said:

"Yes Chip. He is Russian name. Ask where he came."

So, Yuri, again we wonder: what is it exactly you were arrested for and sentenced for? Who did the sentencing? What is your status in the US and Canada?

What passport do you travel under?

Not having the monograph in front of me, I can't tell if the authors
meant a 3 dB decrease _overall_ or merely 3 dB at ground level via
ground wave.

It is my recollection that verticals with poor ground returns
express most of their inefficiency through reduction in very low
angle radiation, with medium angles relatively less affected.

With all good wishes,

Kevin, WB4AIO.

If I run an end fed wire, or a dipole to a tree near my house, can the antenna wire touch the tree branches and leaves, or will this damage the transmitter? I am planning on using an FT-600 on the HF bands with not more than 100 Watt power.

Thanks in advance for you thoughts on this issue,
Hitori

counted on no matter what the wx or moisture, etc.
>
> Serious questions :-
>
> By how many dB would signal strength decrease if the number
> of radials was reduced to 60 ?

I guess about .4 - .5 db. Almost exactly as Roy quotes from the 1937
paper. I had come to the conclusion .4 db could be had every time you
doubled the radials from tests I had run using eznec. Seems to come
pretty close to the 1937 study.
> ----
> Or if the number of radials was reduced to the point where
> signal strength fell by 3 dB, how many radials would
> remain ?

Zero according to the .4 db per doubling estimating. A quick calculation
shows 2 radials would show .6 dbi. if 120 radials were 3.0 dbi. But this
is just quick quessing...As another quick test, I just punched in a 160
vertical into elnec. With no radials over average soil the gain 1.4 dbi.
With 120 radials, 3.4 dbi. Came out pretty close... MK

Hi Jerry,

On Fri, 22 Dec 2000 18:33:04 GMT, jflanders2@home.com (Jerry Flanders) wrote:

>If I understand this correctly, they thought their data shows that a >1/4 wl vertical with only two 0.4 wl radials is only 3db down from one >with 113 radials of the same length over (presumably) typical ground >at 3 MHz.

That may be what people think, but it certainly isnt what most people I know who have tried it both ways "see".

In a test here, two 1/4 wl radials were approaching ten dB down from a vertical with 60 radials laid on the surface of the earth.

WT8Y swore his 160 vertical with two radials was a killer antenna, yet W8NBO with half a ground system (about 20-30 radials in one half of a circle from his shunt-fed tower was stronger here night after night barefoot than WT8Y was with his two radial system.

As a matter of fact, when WT8Y went to a dipole he came closer to NBO (I'm about 600-700 miles from them). One might conclude his low dipole worked better than a vertical, until WT8Y added a bunch of radials to his vertical. He then actually started to beat W8NBO night after night.

No less than a half dozen others have have the same results, so selling me that two radials is only a couple dB down won't work unless you have some conclusive evidence everyone else is wrong.

>Makes me wonder why anyone would ever go beyond 4-8 in an amateur >installation.

I can answer that. Because they want a decent signal.

Why anyone would think the intense fields below and around a sparse elevated system won't couple heavily around the radials with concentarted fields into the lossy earth is beyond my reckoning! Few people would expect a dipole six feet off the ground to not have considerable ground losses, why they think a radial should be different is a mystery.

>What change has been observed by hams who have taken measurements as >they added radials? I think I remember reading reports of how the >performance changed, but I don't remember the results.

I posted my results dozens of times. Someone measured almost the same results at a BC station where an A-B test was made with only a radial change. Many other people have reported the same results. It's old, it's tired, but because a few articles made it in print the myth that a sparse ground system near earth is "better than 120 radials on the ground" will probably never die.

All I can say is I hope ANYONE who goes head-to-head with me in a low band contest or a pileup uses a low dipole or a vertical with less than a dozen or so radials.

I like winning.

Antenna = 1/4-wave vertical at 3 MHz.

Ground conductivity = 5mS.

Ground Permittivity = 13.

Length of radials = 1/4-wave.

Diameter of radials 1/6"

Calculated Results :-

No of Radials dB relative to lossless.
========== ================
120 1.1
60 1.2
8 1.8
4 2.4
2 3.5
1 5.0

Which figures are in the same ball park as B,L & E.

As someone, not an MW broadcaster, asked - what's the point
in having more than 8 radials in average or better than
average ground ?

I have a 475 foot long end-fed wire antenna I shot thru seven trees with a bow and it works fine at 100w. The wire is cheap Home Depot #14 THHN *insulated* 600v stranded copper stuff. Feeedpoint impedances vary a bit between wet and dry weather but I've never had it arc over under any conditions. I've worked the world with it with a barefoot TS-940. There was a thread on the topic here a few months ago "Do trees absorb RF?" (tune DeJa). Test work has been done in the field by the military and there are losses to the vegitation as the frequency goes up, but not to any noticeable extent on freqs below 30Mhz.

Also, I might add something to this. I think those numbers, while theoretically they should be close, are somewhat misleading to the real world results. If a person were to look at those , they might think ,well thats only 2 db or maybe half an S unit. But in the real world I think the difference will seem much larger. If you work a guy on 160m, 1000 miles away with no radials, and are S 5, if you add 120 radials the difference is going to be much larger than a half S unit in the real world I would think. I bet would be at least a couple of S units. Maybe more. And that would make the estimate look flawed, but I think the outright gain numbers have less to do with it than the improved low angle performance with the better ground. It's the same ole deal as in comparing a dipole with 2.1 dbi gain with a mobile ant with much less. And having the vertical win to a certain place. Gain doesn't mean a thing unless it's at the angle you want it. The "good" radial systems give the angles below 15 degrees a real shot in the arm. 2 dbi can be pretty good if you start at 0 or less. With a 1/4 wave and no radials, anything below appx 15 degrees will be -dbi gain. That point will drop to about 7 degrees with the 120 radials. Seems to me a lot of the dx must use these angles below 15 degrees on the low bands. And giving a 2 db shot to the higher angles won't hurt either. I don't know if any of this makes sense, probably not, but I think just looking at the numbers could mislead on the performance gains of adding 120 radials. Or even just 60 for that matter. MK

Hey if you have no other choice, just do it! Doesn't seem to hurt the trees!

I have loaded up and effectively used antennas with the dipole wire elements just flung over tree tops, touching the branches and leaves everywhere and worked the world.

Of course I only loaded it up in dry weather. Didn't think it was advisable in rain or heavy snow.

Didn't notice any problems with the wires laying over the top of dry oak and/or pine trees with 200 Watts fed from an FT-1000 through a balanced tuner connected to ladder line fed to the tree top dipole elements.

Great temporary antenna, and for me... heh, heh... temporary led into a couple of years!

What???

Did I read correctly?

Nathan assuming that he is a "authority figure"! Heh, heh... Meglomania of the highest order...

Now that's a real joke!

Nathan's continuously fractious and obnoxious behavior lead most to perceive him as partaking of desparate attempts to seek approval and credibility, and not as the confident quiet performance of one for whom that gentle mantle has been quietly condeeded by legions of admirers. Methinks he doth protest too much.

I ask, under what circumstances would Nathan's obnoxious and litigious actions be perceived as those of an "authority figure"? Really!!!

An authority figure, "walks softly and carrys a big stick". Nathan seems to "walk loudly and carry toothpicks".

What???

Unless the coax needs to be flexible, you can make some 125 ohm coax out of hardware store 1" I.D. copper pipe with an airspaced 1/8" O.D. center conductor. The impedence will be 124.6 ohms by my calculation [138 * LOG (OD/ID)]. You could also use .5" OD and 1/16" ID for 125.1 ohms impedence. The 1/2" would work nicely with Modified PL259 or Type N connectors. Use some center drilled 1/2" plastic "marbles" for center spacing.

: You can certainly work DX on a low dipole on the lower bands, but it
: is my experience that a low dipole is rarely close to a vertical with
: a **good** ground. Most others who have compared both a good vertical
: and a low dipole agree.

The problem with low level dipoles is that most of the radiation is at
high angles. This is not conducive to long distance communication, although
it can work very well for short hop work.

I thought of this solution when I read the posting, but I didn't feel it
was appropriate given the application. The problem would be connecting
to the homebrew cable. It would be difficult to make connections to it
without adding quite an impedance discontinuity. From the description of
his application, it looks like a predictable and constant impedance is
critical to proper operation. I might be wrong about this and, if so,
and if he doesn't need to bend the cable except a small amount, the
homebrew approach would be fine.

Greetings to the group.
Any thoughts/comments about the portable vertical described in the Jan 2001 issue of QST? I'm thinking about building for QRP use. Guess it's a knock off of the Alpha Delta Outreach. Author describes use from 10-40 meters with various horizontal top pieces for tuning bands.
As I'm not an antenna "guru" I'd like to hear the groups comments reference this particular antenna (pro and con)

Thanks and 73
Terry

I haven't read the article yet, just looked at the pictures. IMO,
the spacing between the coil and the top hat should be increased.

Is it aluminum under the rubber? or fiberglas or plastic? You
can always attach a rod to the bumper and mount the antenna
on top of the rod. A $20 Hamstick works pretty well on 20m.

> Also, never having worked mobile, what do I do for a ground?

The metal chassis is the 'ground'. It is capacitively coupled to
the real ground.

Only problem I had with an EDZ made from the same wire was that contact
with moving branches in the wind eventually wore through the insulation
and allowed the branch to contact the antenna wire itself. This caused
the SWR to wander around when the wind was blowing, but didn't seem to
interfere much if any with the operation of the antenna.

4694. wtd: info on building a simple short wave antanna

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-23 08:07:09 UTC
From: mrhuntnpeckextraletters@home.com
Message-ID: <3a4555c8.900800453@24.2.10.79>
Source record: 174292

I would like to build a simple antenna to pick up am and short wave stations so that I can listen to some of my vintage (1930's) radios.

I was thinking that I could use cablevision wire and outlets inside the house and run it from the top of the roof to one of the trees in the yard about 40 feet away, or to hang it a foot or so above the peak of the roof.

I am in the city. just outside Vancouver . B.C. Canada.

I am wondering if multistrand wire is better, or if single strand wire is enough, and how heavy a guage I should use , and if it needs to be bare wire, or if insulated wire is ok. I understand that a ground wire should be near the antanna just in case it gets struck by lightening, I could use some info on just how the best way to rig this would be. I have plenty of insulators

I am also wondering how much wire is best to use. I could make kind of an L shape by going to a nearby clothsline pole as well. would running it back and fourth to use more wire help, or make it worse?

I have a piece of bronze mesh from part of a paper mill here it is about 2 feet by four feet, and is made with lots of wire, I was also considering using this as well or instead. I have it hooked to my radio in the basement which gets me local stations, but not too much else. can I expect to pick up much more with a better antanna? are there very many short wave stations anyway? I only get a couple now.

any help , or tips would be greatly appreciated .
Phil

4695. Re: K3BU Prison Sentence

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-23 09:10:12 UTC

I asked Yuri why he was sentenced to 5 years of prison--a fact that he publicly stated but did not say why.

I also stated that appears to be compelled to attack people associated with authority, this based purely on his recent attacks on me as an authority on antennas, and extant US politicians, for reasons that make no sense.

That 'authority' issue is an inescapable impression.

As a result of this, Yuri now says he is leaving this NG,(something he claims to have done in the best, but then returns in a matter of days.)

He first did this in 1998 when he made the major transgression--one of many--of referring to me work as "fucktennas". I am appalled and seriously injured by this and other characterizations byYuri-- ESPECIALLY as he has never built, tested, modeled or had anything to do with my work or the independent assessment of it.

The difference this time is one of litigation. Yuri has finally gone over the top. I will not tolerate ANY more of his libel and other claims of injury against me.

If he is a citizen of NJ, as claimed, then he will be served with a cease and desist order in the new year, followed by more serious civil litigation should he not heed the requests stated.

Yuri is correct in that his personal attacks and malicious libel WILL, repeat WILL stop in the new millenium, or the issue of litigation will become a dominant one in the New Year for him.

If he wishes to try to beat me in a contest--a healthy competitive and measurable activity--I would welcome that. However false assertions about my lack of ability; lack of credibility; lack of antenna peformance; and pure, malicious libel just will NOT be acceptable in a public forum in the coming year.

It is up to him whether he can function on a public NG without focusing on me and others in a malicious and personal way.

Cordially,

Nathan Cohen, Ph.D.

From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <9221eviuc1@neptunium.btinternet.com>
Source record: 174298

Let's consider a 1/4-wave vertical erected above the magic
number of 120 radials to be 100 percent efficient.

The radiation resistance of a 1/4-wave vertical is 37 ohms.

If the input resistance of TWO radial is 37 ohms, when the
1/4-wave vertical has only two radials the efficiency will
fall to 50 percent. Only 3 dB down on 120 radials.

The loss resistance of TWO long radials, shallow buried in
good soil is typically 37 ohms.

You can use ground radials that are normally coiled up (small spools w/
alligator clips on the wire to connect them.
THen, use a full 1/5 wave radial.You could make it out of aluminum & clip it to
tj=he roof w/ "Mini" electrical conduit clamps.

Totally non critical for receiving. Just string up the longest and
highest wire "any type " you can. Indoors, outdoors, no matter. Also
doesn't really have to be too long in most cases to do ok. MK

Almost all my wire antennas are run though trees at the ends. My inv L
is supported from a tree. If it were not for trees, I would be in sorry
shape here. Right now, I have appx 570 feet of wire running though
trees. Hardly ever a problem. Never an "antenna" problem, but have
cooked a few tree branches with high power rf when using bare wire.
Nearly legal limits worth of power to do it though. You will see that at
the ends of dipoles etc. I don't use bare wire anymore. MK

No, would be pretty lousy..Using tuners to "tune" mobile antennas where the loading coil is set for another freq is a bad idea. A 30m stick would work great on 40m if you added a longer stinger to tune to 40. If you want good performance, you HAVE to resonate the antenna. I know that goes against some peoples ideas on needing resonance to get good performance, but I think you will find it true on mobile antennas. The tuner should only be used as an impedance matcher if used at all. If you don't want to get out of the car to change the antenna, I would look into a screwdriver. MK

It's a concern. I left a lot of slack between trees in order to hopefully minimize wire sliding & wear. The wire has only been up for about a year and half and no problems so far but I certainly don't expect it to last 30 years like my old tower & beams did. After I put the wire up I ran into the Wireman's ""Silky Toughcoat" series of insulated stranded Copperweld wire. The insulation is amazing, wire strippers bounce off the stuff. When I have to replace the existing antenna I'm gonna use the Toughcoat, should get a lot more years out of it than I will from the THHN.

Another factor in making good joints is using 63/37 alloy solder, NOT 60/40 or something else. 63/37 solder is eutectic, which means it has the same melting and freezing point. Other alloys, believe it or not, melt and freeze at DIFFERENT temperatures and this can lead to fractured joints because they have a longer time period in which they could be disturbed. 63/37 goes from liquid to solid almost instantaneously (close enough for our purposes).

4715. Do Trees Absorb RF ?? (Re-visited)

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-23 16:07:10 UTC
From: cathexis@erols.com
Message-ID: <3a44c719.215961597@news.erols.com>
Source record: 174312

Greetings,

I'm aware of a similar thread that's current on the ng now
and I also know an earlier thread has been referenced as well, But
would like a couple of questions answered here please.

1. If a vertical is supported by a sizable tree, will the tree create a
substantial "null" in the radiation pattern? Assume the antenna
gets only physical support from the tree but the radiating element
is "shielded" from contact.

2. If the tree would create a null or "dead-zone" for your radiated RF,
what would be the effect of splitting the transmitted RF signal into
an array of 2 or 3 verts., each supported by a separate tree so as to
negate the effect of dead-zones? In other words, if placing a single
vert. on the so. side of tree #1 "deadened" northward radiation
could you get around this by splitting the signal to a 2nd vert. placed
on the north side of another tree?

3. If it was desirable to use an array of 2 or 3 verts. , can they share

radials? If not, can those separate radials touch or overlay one another?
Assume the radials are just buried an inch or two in the soil at most.

Final Question: I'm looking for some kind of graph that would show how
much PEP a given #guage wire or other radiating element could support.
For instance, if 14 AWG stranded will safely carry 100W PEP, what would
I need for 500W ? 1 kW ? etc. You've probably guessed by now that I'm
considering a homebrew vertical(s) and want to plan ahead for maybe getting
a linear sometime in the future.

Many THX. and Merry X-mas,

Andrew/ KG4JBM

I hope this makes sense. If not, my apologies and say so and I'll try to
reword it to make it more sensible.

The most satisfying way of finding the input resistance of a
shallow-buried ground radial is to measure it.

So-called, hand held, antenna analysers are sufficiently
accurate and available enough to do the job.

I am fortunate enough to be able to calculate it.

Unfortunately there are far too many old-wives, wafflers and
baffle-gabbers who waste people's time on this newsgroup by
disseminating ill-informed nonsense.

The problem for genuine students, radio novices, etc., is
how to distinguish between the overwheming masses of facts
and fiction with which they are inundated.

What is the approximate Z of common 110v power cord? Years ago, hams used to run it as a twinlead type feedline for dipoles (it was called zipcord then), and it seems like it was around 75 ohms, or so. Is the modern stuff, with better insulation, still a good dipole feedline in some applications?

4721. Re: Impedance of PL-259 and "Barrel" connector?

I think "eutectic" only means that this particular ratio (63/37) of
the components of this alloy has the lowest melting point of all
possible ratios of these components. In other words, 63/37 is the
lowest melting temperature solder made of these two metals.

The ARRL Antenna Book (15th Edition) contains an article on zip-cord antennas.
The impedance in some tests ran around 110 ohms, the velocity factor about
69.5%.
It could be used, however the bad news is the line loss -- about 4 db per 100 ft
at 14 mhz!

If you want to feed a dipole, or any other antenna cheaply, 300 ohm twinlead
works very well.

Given that the "true facts of life" may not be known in our
lifetimes, there doesn't seem to be any conflict between
making a profit and disseminating good advice. In fact,
disseminating good advice probably increases profits. Is
there something in particular in The ARRL Handbook that
you object to?

It stays close enough to "perfectly horizontal". The two foot
shaft between the top of the screwdriver and the top hat is
very rigid. I'll measure the "equivalent-radiator" length and
get back to you.

The dielectric is lossier at RF than the dielectric in coax and the
ohmic losses are high because Z0 is low. It's not a good choice for
a transmission line.

No such charts exist because the maximum current in a specific antenna wire depends on the antenna design. Using Ohm's Law and assuming a 20 ohm feedpoint impedance for a quarter wave vertical and 1500 watts of RF the maximum current would be 8.6 amps and would be located at the feedpoint. Any #14 wire hanging in free air or in trees will be loafing with 8.6 amps being pushed thru it. Use #14 for HF wire antennas and forget the "engineering".

In TV news, an Authority Figure is any character a harried behind-deadline reporter can scrape up to go on camera and claim special knowledge. Take the cellphone controversy and cancer, for example:

Cut 1, 1st A-Fig: "I teach Culinary Arts at Berkley, and I say cellphones cook your brains and cause cancer".

Cut 2, Man on Street reacts: "Jeez, I'd better confiscate little Johnny's Erricson right now, before it bakes him alive!"

Cut 3, 2nd A-Fig (to create tension): "I teach Remedial Astrology at BU's Metro Division, and belive me, that first meatball you interviewed is full of stewed pork rinds! Cellphones never hurt anyone--and they may even CURE brain cancer by killing tumor cells!"

Cut 4, Reporter (with a scare the poo out of me and you wrap-up): "Well folks, this issue won't be resolved anytime soon! Meanwhile, many believe a national tragedy is imminent as milions of these tiny flip-top fryolators insidiousy incinerate the intellegence of our youth! Live in Silicon Implant Valley, I'm Phil N. DeBIanc for CBS news".

Anybody wanna be an "authority"? It's easy. Just go....figure!

In recent years, the ARRL Handbook has largely been written by volunteers, many of whom are professionals in the fields they write about. The editors are surely interested in making a living and feeding the family, as most of the rest of us are. But one of the better things about capitalism is that their desire to feed the family tends to enhance, rather than reduce, their efforts. The directors serve without pay and at the pleasure of the members, so it's not clear how they would profit by putting false information in the publications. The ARRL has no shareholders, unless you want to count the members as such. But they pay, rather than profit, regardless of the content of the publications.

The true facts of ARRL life haven't been accurately represented by your posting. Much as it must irritate, there are good and accurate sources of information besides Reg, and all that is not Reg is not bafflegab or old wives tales. In general, the ARRL publications (particularly the Handbook and Antenna Book) are very good, and real bargains for the price.

I don't know. The B & W antenna is prized because of its broadbandedness. Using lossy feedline will accomplish the same purpose -- it doesn't really matter whether the resistor is in the feedline or the center of the antenna. B & W users have shown that some folks are glad to trade a few (or a lot) of dB for broader bandwidth. This is just another way to do it.

It's the composition which is completely melted at that lowest temp.,
but for instance, 60-40 starts to melt at the same temp, with solid and
liquid existing together over a range of temps. Look at a tin-lead
"phase diagram" for further info...you can probably find one on the net!

There's one, for example, at
http://www.umist.ac.uk/MatSci/research/intmic/phase/pbsndiag.htm

Cec, there's a difference between making a profit and making
a living.

Profits are invariably made, by definition, at somebody
else's expense.

I have nothing more against ARRL handbooks and publications
than I have against any other similar amateur handbooks and
publications. The USA is only one of several countries which
produce them.

USA versions are not sufficiently reliable to be quoted from
as an authority on the subject of radio engineering. This is
not surprising as they are produced by and for amateurs. As
I've said before the ARRL Handbooks are not Bibles or
Korans. They are not worthy of being worshipped. And
neither are the corresponding RSGB publications except that
they are a little nearer to qualifying.

My main objection to what occurs on this newsgroup is the
manner in which many questions are answered by referring to
the ARRL. Who the heck are they anyway ? If anybody has an
answer to a question then by all means give it. If he
hasn't got an answer then he should keep his mouth shut.

To refer to some other source of information is mostly a
form of bragging or name dropping. "I don't know the answer
but I know somebody who does." A recommendation by an
unqualified recommender is of little value.

Most answers to questions which refer to somewhere else are
a waste of bandwidth. If the questioner had easy access to
the reference material he would not be asking the question
anyway.

I hasten to add that I own no shares in any rival
publications. Please take a pich of salt and carry on as
normal.

Don't have one.
>
> I am fortunate enough to be able to calculate it.

Unfortunatly, that doesn't do me much good here. I'm a dummy who can barely count. But really, I've never really had a need to measure it. It's not going to help my system to know exactly what the ground or radial input resistance is. I know it still needs to be improved over what it is. So measuring it is kind of a waste of time, unless I'm just curious to know. I'm more bottom line performance oriented. Either it's working well, or it isn't. But, I'll be glad to go out and measure it if you have a fairly easy method to use, not needing any fancy test gear.

> how to distinguish between the overwheming masses of facts
> and fiction with which they are inundated.

Very true. But if what you say is true, that the difference between two radials and 60 or 120 is only appx 3 db, why all the disparaging performance reports? Why would Tom report a 10 db spread between 2 radials and 60? Why would almost all the people that use verticals with small radial systems have lousy results when compared to the larger radial systems? An inquiring mind wants to know...I admitted my past statements were likely baffle gab when I posted them, but to me , they still make the most sense. Why would people see such a large difference in performance if the enhanced low angle performance didn't make the difference? Obviously the difference in outright gain is not all that great. So if thats the case, there must be another factor involved, and to me it would seem to be the enhanced low angle performance, or lowered PBA. Of course, this would apply more to far off DX than close in stuff which is usually the goal in using a vertical in the first place. If you know of a way to make 2 radials act like 60 other than raising to the

1/2 wl height, I sure wish you would fill all of us "dummies" in. I'm all for saving wire. So far two slightly elevated 1/4 wl radials, and a few shorter ones are not working that fantastic here. Does ok, but nothing to write home about. Makes me wonder who is really spreading the old wives tale here. I may not be able to explain what I'm doing, but I can tell what works and what doesn't. The vast majority of small radial system antenna owners give their system a thumbs down against even a fairly low dipole. Something is wrong there, when all the full radial systems, or elevated with the proper number of radials, eat dipoles for lunch at any distance. What are we all doing wrong? I'm open to any suggestions. At appx 15 bucks per 500 ft of wire, I could save some serious money. If I had my way, I'd much prefer no radials at all. MK

Phil,
Mark pretty well said it correctly. The most wire, as
high as you can get it.
At one time antennas for 'listening' were strung around
the eaves of a house on stand-off insulators. They worked
as well as most omnidiretional antennas.
Unless there is a particular station you want to hear
which would require a directional antenna, any of your suggestions
should work fine. You might concider an insulated wire with
a color that isn't obtrusive, and the size doesn't make any
difference.
Using a distribution system in the house makes things
more complicated. I don't think you would need any special
cable/wire, the same you used for the antenna should work as
well as any.
Merry Christmas

All these postings on this thread seem to overlook a credible,
consistent definition of "zip cord."

In the 30's and 40's, it was rubber/cloth insulated lamp cord (usually
green and yellow - remember?). It worked but was very lossy. But it
could be used and that is where the legend began.

In the 50's and later, it became "POSJ" plastic insulated lamp cord.
Still useful if not technically acceptable for many applications.

Lord knows what the insulation is these days, but I would bet that it is
better than cloth and rubber.

Some "zipcord" will have #18 or smaller wire, depending upon length and
price.

Other "zipcord" may have #16 or larger wire, again depending upon length
and price.

So, what is "zipcord?"

Beats me, but I think that the conventional wisdom of it being useful in
a pinch for a somewhat lossy but not unusable feedline is correct.
Certainly, stripped into separate halves or wires for a dipole, it will
work as well as any other insulated wire for a flat-top or inverted-V.
The classic emergency dipole made by splitting zipcord at one end into a
dipole, tying a knot in the center, and feeding it with the remainder
still stands as a usuable alternative to a "proper" dipole.

Hi Craig, I modified a discone a while back. I made a new vertical element from a mobile whip. It was cut to 54 inches and works great. I had to make an adapter to fit the 3/8 thread of the whip to fit the 1/4-20 thread of the horizontal element mounting setup. The sloping elements were already long enough on this ant, but yours may not be 1/4 wave if the lowest freq is 75Mhz. You may have to extend them to around 54 inches.

Maybe you're right, Roy. I could sure undercut B&W prices if I use
zip cord to feed a dipole.

I have one on my car and it works great!

People try to put a Outbacker on a mag mount or install it
incorrectly, then complain it does not work. Like any antenna
Grounding is VERY important. On my first attempt at installing the
Outbacker, I cut some corners and could not get it to work correctly.
When I went back and did it right. It now works great.

Not everyone has the space and height availablr to permatly mount a
screwdriver antenna. I use a Hustler quick disconect on my Outbacker.

Hi Reg,

Can you tell me how to measure the ground losses around my vertical
using a hand-held antenna analyzer?

That would be a very useful thing to learn.

> I have one on my car and it works great!

"Works great" is very subjective. According to actual 75m mobile antenna shootout measurements, an Outbacker radiates 88% less power than a good bugcatcher or screwdriver. That means if a good bugcatcher radiates 100 watts on 75m, the Outbacker radiates 12 watts. How can that possibly "work great" on 75m? IMO, the Outbacker is just about the *least* bang for the bucks in mobile antennas.

For instance, the 1dB improvement that the Outbacker has over a Hamstick on 75m costs $200. Anybody want to pay me $200 per dB?

Hi Reg,

I take it you are an experienced low-band operator. A person who has
many antennas to compare, and who does so frequently.

Please, as a demonstation of how accurate and thorough you are, tell
me how to measure ground loss with an antenna analyzer.

Maybe you could also tell me how to accurately measure soil
conductivity in a small area wher the radials sit.

Rick:

Yeah, OK... OK... OK... I see now... from your examples I see that you allow a very modern interpertation of authority figures, I like to refer to those as "Neo-Authority Figures", where egalitarianism reigns supreme and anybody can be an "authority figure". But I am sure that Daniel Webster or the OED would roll over and groan at such a modern definition!

Previously, I was thinking along more traditional lines for the definition of "authority figure", you know like the Chief Justice of the Supreme Court, or The Pope, or the Captain of any Ship at Sea, or anybody's "Mom" or... "wait until your Father comes home!", or your old boot camp Gunnery Intstructor, Drill Sergeant, etc...

I agree that Nathan fits in the Neo category, but somehow I don't think he rates in the traditional category yet...

Just an opinion... from one who believes that authority is earned and awarded by others, and not gained through self-anointment.

Happy Holidays...

Fractals:

Fractals - simply the visible tracings of the limit cycles emitted by
non-linear processes and systems, sometimes observable, sometimes
controllable, sometimes not, but always beautiful.

"But only God can make a tree!"

We will all have to admit that trees certainly have forms reminiscent of
fractal geometry.

I believe that Mother Nature produces many of her most beautiful creations
using fractal methods.

And so... I believe that the forms of trees qualify to be called fractals.

Anyone ever measure the bandwidth and number of resonances of a big old Oak
tree? How about a Sycamore, or Cypress?

I think I know how he will go about it as I have his earthres program. I had remembered that a little while ago and checked it out again. But the only thing is here, I keep getting varied results trying to use different metering. Seems you need quite a bit of voltage and current to get an accurate reading. If I use my power line ground as a zero reference point, as one method, and try to use different meters to measure, I get different readings with each meter depending on the voltage used for ohms measuring, etc. I have a 45 volt Bell telephone ohm meter with reversable polarity, but it's resolution is too low for the ham use it seems. With that meter, I can stick a 2 ft car whip anywhere in the yard, and show a dead short to the power ground. Now, I doubt my situation is quite that good. So that means to make an accurate measurement, I need to use an external power source, and measure the current and voltage between different points. Seems to me, I could just use the power ground as a ground reference point and run a light bulb off 110v and then measure the current and voltage. Then stick a rod out in the yard, and measure again, except use the ground rod as the ground return and measure the voltage drop. I don't know if that would work well or not for accuracy. Dunno, it's kinda interesting, but still a bit of work to measure something I know will need to be improved anyway. I'm generally too lazy to go though all that. But even if I get an accurate measurement, what does it do for me? My idea of measuring the saturation of a radial system is to note the bandwidth. When it quits shrinking, you have enough radials. I can tell that from here in the shack without running any resistance tests outside. Being generally lazy, I tend to like that method. MK

Hams support wire antennas, such as Ls, from steel towers. There usually
isn't a problem unless the tower is resonant on the wire operating
frequency.

Can you grid dip a tree?? Or, use a detuning stub???

Peter

What you are approaching is known to geophysicists as Vertical Electric Soundings, or just "resistivity" measurements. The complicating factor is that the apparent resistivity (and measured resistance) on the surface is affected by the resistivities of various layers of soil and rock to a surprising depth.

Field data are collected using a logarithmically spaced array of electrodes, and the interpretation is a fairly arcane art. The old traditional method is to plot the measured values on log log paper, then use books of overlay curves to find matches to various parts of the measured curve, eventually coming up with a layered earth model with each layer's resistivity and thickness.

There is no way to go from the field data (measurements) to a model; there is a way to go from a model to the measurements that you would see. Computer analysis involves starting with a guesstimate for the model, then calculating the measurements that would result, comparing those calculated values with the real values, and perturbing the model for a better fit in an iterative method of successive approximations until you get a solution that is within your specified limits of uncertainty, usually expressed as an RMS error (difference) between the calculated model results and the actual field data.

Many years ago, I developed a program to do just that, but that was many years ago, and HP doesn't even make the workstations on which it ran anymore (I don't think that they even remember making them...).

The values that you will measure at the surface are affected by various layers including the surface soil, the deeper soil, the underlying rock and/or deep soil layers, and so on, and the effects are surprisingly strong. In general, a layer will affect readings at electrode spacings considerably shorter than the layer's depth, depending upon the resistivity contrasts between various layers.

Undersoil topography will also affect the surface readings quite a bit.

It is a fairly complex subject. Most engineering geophysics texts
will discuss it.

This whole concept is the original contribution of the Schlumberger
brothers, who were very interested in the electrical properties of
the Earth, and who took time from the family vineyards to experiment.

And all of this is just the DC characteristics....

Well said, and in my perception, entirely true, although the
soi-disant "authority figures" often seem to be far too full of
themselves to see the essential truth.

Thx. for those quick replies all. Brian, you're right I
was complicating things; Reason was if the trees would be
a problem then answers to the other questions would've had
some bearing on finding a workable solution. Doc, thanks for
your answers as well: You're always helpful and rarely cranky!
<grin>

I was concerned because IF I put up a vertical, one
idea is to have it very closely held to the tree and wondered
if it might not create a large null as it was so close to said tree.
Your replies tell me otherwise and I thank you.

I've had a lot of trouble with my random and my dipole
in that they need to be strung over multiple trees and are really
too high up to make installing insulators feasible anywhere save
the ends. Each has snapped (or dropped because a supporting
limb snapped instead) from wind action kicking the trees in various
directions at once. I'm sure you're familar with it. I don't intend to
trash these antennas. Instead, one reason for putting up a vertical
is simply because I only need one tree for the top anchor and reason
it might be less stress on the physical structure than 4 or 5 trees going
every which way at once.

14 AWG wire inside any flexible tubing (garden hose ?) should
have enough give to move with the tree and even if it drops it seems it'd
be a lot easier to throw back up than some dipole that's wind damaged
and dangling in two different places too high up to reach (like my current
one after last week's windstorm). Anyway, that's where my little mind is
drifting towards this week. Whatever I end up doing, I can assure you --
the solution will be neither expensive nor ideal. Thanks guys.

> 'Doc

I didn't see the original post but I'd like to add to Doc's
reply. If you chose to string around you're house or over it, PLEASE
don't get that wire anywhere near your power line. No matter where
you end up placing it consider: If the wire snapped in a wndstorm
could any part of it end up draped over your power line feed to the
house. If so, move the wire elsewhere.

As to color, I use blue. It looks very bright and noticible up
close or on the ground waiting to go up. But once it's up in the trees
it's very hard to spot againest the sky even for me the guy who put
it up. Once, my XYL complained about how one leg of my dipole was
gonna be tied off to a tree in the front yard:

> " OH Honey !! Not in the front yard ! Andrew,...No. No ! "

I took her out and said ;
> " Point to it ."

She couldn't. And it's still up.

Well, it all depends on losses, and where the radiating currents are
located, I think. I have a screwdriver and it is a good antenna, but it
isn't for everyone or every occasion. At this time, there is no auto-
tuner for the best screwdrivers (since the Yaesu screwdriver is too
lossy, and the Screwdriver Antenna Memory doesn't auto-tune).

I'm experimenting with two different directions - one is to automate
the tuning of the Screwdriver, and the other is to do experiments with
a center fixed-loaded antenna and an autotuner at the base. While the
tuner-base center-coil antenna may not reach the screwdriver efficiency
I suspect it can easily outperform many currently common HF mobiles
including the helical whips, the ferrite cored coils, etc., while being
easiest
(and safest) to use on the highway.

Back before ham radio became an efficiency engineer's playground
(pre-WW2
- I wasn't around but have discussed at length with some folks who were)
twisted lamp cord (no zip-cord in those days) was commonly used to
directly feed 1/2wave dipoles via a link of a couple turns on the cold
end of the plate tank. Nobody knew what they loss was and fer sure they
didn't worry themselves with it since the scheme worked quite well.
Wailing about "What's my SWR" was also unheard of. The elite used open
wire feeders and a HB tuner.

Right, and this is what you don't want - a range of temps with liquid and solid existing together. 63/37 doesn't have this and that's why it is preferred.

Don't feel bad if this is a little puzzling. The solder industry took a long time to figure it out too.

Check the back side of the tuning capacitor. There should be at least two screwdriver adjustments, one of which will be for the AM oscillator. I'd guess you can turn it enough to get 10 more kHz. Good luck.

For only one band, a $25 Hamstick will do quite well, but for a little more and multiple bands, I'd recommend a Hustler 4-BTV or 5-BTV. I used the 4-BTV on my 29 foot fifth wheel for about a year and it was great. This of course has to be taken down when in motion, where the Hamstick wouldn't. I bolted a water pipe flange to the rear bumper and screwed a two-foot piece of water pipe into that for the actual mount. The fifth wheel was big enough that no separate radials or ground connection was necessary.

Your advice is poorly motivated but very good in execution. For the fact of the matter is that Yuri has legal problems in 2001 if he does NOT cease his activities against me.

It matters little to me what motivates good NG behavior--but realize that this diligence to stop these attacks against me is an ongoing situation and legal matters WILL be used to stop these attacks.

Yuri--

If ALL you were interested in was 'ham radio' you would not have focused on me for personal attacks; malicious libel; incorrect and misleading statements and characterizations; incorrect and ignorant comments to a New York Times reporter; and so on.

You have had 3 years to voluntarily end this behavior; the voluntary option indeed disappears with the new year.

It is 'up to you' only for a short time more, and with NO--repeat NO-- further attacks against me on this public forum.

Nathan Cohen, Ph.D.

Exactly my point. I asked for details and received none. Just more malice stating that I have no credibility; my antennas don't work; and so on.

If you read Yuri's comments alone you'd get the impression that--I-- was sentenced to prison for 5 years instead of him!

Yuri has elected to get off this NG. That is irrelevant to me. But he WILL stop his attacks.

That would depend on the length of the tail and how the dog holds it, down,
straight back or up. A husky with a curly tail ought to give you circular
polarization, great for sat. work. ;<)

K7JEB uses an SGC-230 with a base-loaded bugcatcher coil. It works
well for changing frequencies within a band. He still has to manually
change bands by changing the tap on the coil.

Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.amateur.misc

I have had a Cushcraft ground mount HF in place for six years now. It still works flawlessley on all bands, including six meters and, surprisingly, two meters!
When I put this antenna together I did stray from their instruction a bit. I liberally coated all the contact points with a compound called De-Ox. This eleminates oxidation due to things such as acid rain and other elements.
I do check the antenna every two years with an MFJ antenna analyzer and I have had to readjust a couple of the coils...usuallly the 17 meter one. This antenna does flex in the wind and despite making all the connections tight, they do tend to "migrate" a little.
Suggestion: once you get the antenna set, mark the location of the coil clamps with a number two lead pencil. You can then loosen the clamps and slide them back into position and the markings seem to stay in place despite rain, snow, etc.
The only gripe I have with Cushcraft is that they charged me sixteen dollars for the six meter add-on. This consisted of nothing but two little aluminum clamps and a length of coated wire. That was kind of a rip-off and I let them know. They did not respond.
One last suggestion. Install radials under the antenna! This is important. I buried a couple dozen lengths of #12 coated household wire about two or three inches under the soil. These reflectors need not be of any specific length, though some purists may argue that point. It is important that you do this for the antenna to work well.

Name and call not given.

Source record: 174049

The problem, always, with shortwave and AM reception, isn't getting enough signal, it's minimizing the man made noise. Don't worry about getting a lot of wire up, or what shape the antenna is, concentrate on keeping it away from local noise sources. The biggest source of noise is the AC wiring in your (and your neighbor's) house, it conducts noise from more distant sources right to the area where your antenna might be. In your house, the biggest noise sources are your television (and computer monitor), your computer, light dimmers, touch control lamps, motors with brushes, neon signs.

You are generally better off putting up less wire, but getting it out in open as much as possible. You should use coax to run from the antenna to the receiver. You could use your cablevision system to distribute the signal around the house, however the splitters won't work at these frequencies, so you will have to hard connect the coaxes together to get where you want to. I wouldn't use T's because the unused legs are a possible entry points for noise. This means that just one outlet would be active at a time.

You also have to be very careful not to conduct noise back out to the antenna on the outside of the outer conductor of the coax. I try to take the coax straight down from the antenna to the ground and run it on the ground back to the house (buried or in buried conduit is even better). Elevated runs tend to turn your coax into part of the antenna. Ground the shield of the coax where it enters the house and where the coax meets the ground under the antenna. I also float the radio and anything connected to it by using an AC ground lifter with the ground terminal unconnected.

You might also look into loop antennas, especially for AM reception. They have the advantage of being able to null out a signal in one direction (actually two directions 180ï¿½ apart). One of the best made AM loop antennas is made by Kiwa, of Yakima, Washington.

I use a homebrew amplified whip antenna for LF and SW dx'ing. There are a number of similar commercial antennas available. They have the advantage of being generally small in size, so they are more easily located in an area of low local noise.

You can also take a portable radio, tune it to a relatively quiet AM channel, and go around your back yard "sniffing" for relatively quiet spots. Be sure to do this several times at different times of day and on both weekdays and the weekend so that you get an idea of how the noise situation changes.

Good luck and let us know how things turn out for you.

Basically an outbacker and a ham stick are about equal I would think.
Tne outbackers are just hamsticks with the abilty to change taps. A good
screwdriver should outdo either one. But you can improve the hamsticks.
How long is the stinger whip on your antenna? If it's short, you can
definitely improve the antenna by using a longer stinger, and reducing
the amount of windings. Or you can just take a 10-15 meter stick and use
the longer whip to tune for 20m. A 10m stick on 20m, is lot better than
a 20m stick on 20m. It's always better to use capacitive loading than
inductive loading if it's possible. Also the helical sticks need the
capacitance on top to work decently. A helical stick with a little
stubby short stinger is going to be lousy almost every time. A top
loaded 10m stick can be tuned to 20m with about 2 ft of stinger. Also
your metal railing mount probably leaves alot to be desired I bet. Make
sure its grounded to the frame real good. I assume you are talking about
a mobile. MK

Source record: 174057

Dear Tom,

Please stop putting out your smoke screen. It is not "ground loss" we are discussing the measurement of. It is the "input resistance" of a radial. It is measured in ohms. I'm sure you have an impedance bridge of some sort. At a pinch you could make use of your SWR meter.

The radiation resistance of a 1/4-wave vertical is 37 ohms. Do you agree ?

If a 1/4-wave vertical antenna has only one radial and the input resistance of that radial is 37 ohms (a common sort of value) then the radiating efficiency is 50 percent and field strength will 3 dB down relative to the ideal system.

If your soil is poor and the input resistance of the one solitary radial is 111 ohms, then field strength will be 6 dB down, or one S-unit, relative to the ideal system.

According to John Cleese I should now be granted a Cambridge 1st-class honors degree in the art of stating the bleeding obvious.

Hi Dick,

Lightning has significant energy from a few dozen Hz to many MHz, with
peak energy at a few hundred kilohertz.

The best idea is to just design the system correctly with that and
mind.

That aside, I'm sure a dc resistance test is a lot more useful for
lightning than a 2 MHz and higher transmitter...although it still may
mislead you into a false sense of security.

For example, what if I had a 600 foot deep "ground rod" in normal
soil?

At DC it would look very good, yet most of the energy in lightning
wouldn't even see anything but the forst few feet of the "rod".

First, let me say I hate to disagree with my friend Reg. I admire
Reg's confidence and superior attitude, and especially his ability to
retain it when he doesn't know what he is talking about.

Putting my praise of Reg aside, soil characteristics vary widely with
frequency. What you measure at 60 Hz has nothing to do with 2 MHz.

One poor fellow in SW Michigan was always busy measuring people's
ground conductivity using the light bulb thing in the Handbook. He
concluded that his friend's soil was almost 200 mS/m while his, a few
miles away, was about 1 mS/m.

Bizarre tests = bizarre results.

Everybody knows that soil conductivity is liable to increase
or decrease with the depth of the various layer
compositions. Its obvious. So what ?

If your measuring electrodes are only a few feet apart, and
only a few feet deep, then the measured soil resistivity
will be that of the volume of soil you are REALLY interested
in - ie., down to the few feet of the HF skin depth.

Furthermore, if measurements are made at RF or HF then the
relative importance of the conductivities of the various
shallow layers, if there are more than 1, is automatically
sorted out.

A practical analysis of what is involved is more simple than
an academic, armchair, gazing up at the ceiling, study might
indicate.

There's no need to complicate matters by testing between
giant electrodes spaced miles apart where the conductivity
of the Earth's molten core might have some effect.

It may be of mild interest I have measured the impedance and
voltage between electrodes spaced 2500 miles apart, on
either side of the Atlantic. But I can assure you the
results have no bearing on the present discussion topic.

If it reads open circuit at 60 Hz, does that give a clue about what it might mean at 2 MHz? I think it does. If so, can the capacitance to ground alone at 2 MHz be enough to assure a good ground? I think not.

If it reads a very low value, say 10 ohms, at 60 Hz, does that give some indication about the basic quality of the ground connection at HF? I think it does. Especially if the lead wires are short, low inductance straps.

Based on experience, I think a low 60 Hz measurement does not tell the whole story from 2 to 30 MHz, but if there is no further info, it is still worth something, and not worthless.

We don't always have to be rigorously scientific about everything, especially when characterizing ground conductivity, even approximately, over a wide frequency range means more trouble than hardly any Amateurs want to get involved with.

==========
Tom, how do you know ? That's a damning statement.

Have you ever measured earth resistivity at 60 Hz and at 2
MHz and studied the relationships ?

Or 30 MHz ?

As I recollect, your preferred method of determining ground
conductivity is to set up at great expense an LF or MF high
power broadcasting station and then take ground-wave field
strength measurements at distances of every mile from 1 up
to a 1000.

True on the higher bands, but on 75m an Outbacker is about 3dB
better than a hamstick. On 75m, an Outbacker is about 9dB down
from a good bugcatcher or screwdriver. On 75m, a Hamstick is
about 12dB down from a good bugcatcher or screwdriver.

So far, it has been my experience that things which "everybody" just "knows" are usually wrong.

> If your measuring electrodes are only a few feet apart, and
> only a few feet deep, then the measured soil resistivity
> will be that of the volume of soil you are REALLY interested
> in - ie., down to the few feet of the HF skin depth.

No, that's not true. The depth and the extent of the soil that affects your measurement is more than you think, and the effect is more complicated.

To find the resistivity of that surface layer, you have to measure at several spacings, then do the exercise to resolve the layers. That's the only way to get there, and it is not nearly so simplistic as you make it out to be.

> Furthermore, if measurements are made at RF or HF then the
> relative importance of the conductivities of the various

> sorted out.

Measuring at the frequencies of interest is good.

> A practical analysis of what is involved is more simple than
> an academic, armchair, gazing up at the ceiling, study might
> indicate.

My point exactly. And I have done a lot of practical, applied, in the dirt resistivity surveys. So, you really should get awsay from your armchair and plant some electrodes.

> There's no need to complicate matters by testing between
> giant electrodes spaced miles apart where the conductivity
> of the Earth's molten core might have some effect.

When the discussion degenerates to wild straw men from the hinterplanets, it is time to leave.

If you take the time and make the effort to leave the armchair, then you will find that there is a large, rich body of knowledge and expertise in the field of measuring and determining soil

resistivity,-- real, in the dirt, practical expertise and applications. I pointed you in that direction. It does not depend upon your visitng it for its practicality and validity. But the practicality and validity of your results depend upon your visiting that body of knowledge and understanding at least part of it.

Source record: 174067

I thought I would connect a few recent themes with a dash of seasonal good will.

I recently constructed a scale model of a fractal antenna for 70cms - i.e. I bent a piece of wire a few times. I put this down to help decorate the house for the festive season and when I returned I couldn't find the aerial anywhere at first.

And then I saw that my son had fixed it to the top of the "Christmas" tree! I have to say it makes quite a neat "secular" kind of star. [I guess that puts it in the public domain, so no patent rights for me...]

But it raises quite a few questions about the effect of the nearby branches [and for that matter, other nearby Christmas trees]. Will it still have the alleged gain associated with this design?

And if you're in a house of some opulence, is it worth stacking two Christmas trees for a 3db gain?

For those who don't seem to believe in fractal aerials any more than they believe in Santa Claus, I open the possibility of using this mounting for more conventional vertical designs. In this case the fairy light wiring can provide useful elevated/drooping radials.

If nothing else: just let your neighbour try complaining to anyone that he believes your Christmas tree is breaking through on his television...

Wishing you all the best greetings of the season,

Bill, G4ZRB

In northern Virginia, where I did many mediumwave proofs of performance, the snow was generally of the "wet" variety, with significant melt and ground wetting within a few days at most.

Snow always meant significantly increased conductivity and ground wave field strength in my experience there.

I have no experience with measurement during dry, powdery snow conditions which dominate some climates in the Winter.

With all good wishes,

Kevin, WB4AIO.

Hi Emory,

I have the (I think 160 cw model) cut for 80m but the catalog says you can use it for 160m as well. The antenna works quite well even compared to my yagi and Inverted L. The only thing I didn't like were the crimped on PL 259 connectors. I was getting intermittent poor SWR and it was traced to poor electrical contact of the shield on the crimp connector. Fifteen minutes later a new connector was soldered re-attached and the antenna is FB. I think they are good performers. I use it on all bands up to 10m with a Tuner.

I tend to agree there. It's nice to know I guess, but from a practical antenna standpoint I assume the worst and go from there. I think thats a safe way to go if you want consistant results. Thats why they still run 90-120 radials in this area of good conductivity. I'd rather be overkill than underkill. Take a survey of all the people runnng antennas with underkill radial systems on the low bands, and most say they don't work well. Almost to a person. Take a survey of the overkill bunch, and the opposite seems to be true. To me, using the bandwidth as an indicator of radial effectiveness should be pretty accurate. Normally, when you approach saturation, adding more radials will cause very little reduction of bandwidth. Being as this test is done at the operating frequency, I don't see how you can go wrong. I have no problems with Reg's math. But I don't share his assumption that most ground is good enough to get away with 2 radials and have good DX performance.
Take this excerpt as an example:

<If your soil is poor and the input resistance of the one solitary radial is 111 ohms, then field strength will be 6 dB down, or one S-unit, relative to the ideal system>

Now, I have no trouble with the theory of that at all, but if thats a "poor" ground and you only see 6 db difference, that means most of the people in the US must have HORRIBLE ground conditions. Tom for example saw about 10 db from 2 to 60 radials. Thats means Tom's ground must really be the pits going by Reg's example. So you see my problem here. While Reg's math is correct in theory, it doesn't really seem to match the conditions and results we see here in most cases. I wish I had 60 radials ready to go so I could test against two here.But I don't at this time, and also my radial system will be a bit lopsided as the antenna is on one end of the yard. I can only cover about 270 degrees. The next door house is in the way of the other 90 degrees. So anyway, to each his

own I guess, but I think I will stay with the overkill route and not have to worry about "what if????" That antenna's main job as designed is to work low angles on 160m. I don't want to cripple it by being chinchy on wire. Also if you use a shortened vertical the ground system becomes even more important. My inv L is probably more on the order of 10-15 ohms radiation resistance rather than 37. And my antenna still full length.
Get one of these real short verticals running 5 ohms or less and the ground system is very critical. I guess my whole "bafflegab" on verticals stems from the people that I hear that try them and say they don't work, but they don't bother to put in a decent radial system, or use the proper amount of radials on an elevated system.
There is no free lunch. If they want a "good" vertical , they have to do the work involved to make a complete antenna. If they are satisfied with a "so-so" vertical, then yes, I guess they can get by with less, but place the blame where it belongs when it doesn't work up to expectations. MK

How long was the stinger on that 80m hamstick you tried? They make alot of different varieties. Some much better than others. They make a "bigger coil" version stick with a fairly long stinger I bet would fare well against the outbacker, but if it were one of the standard "slim stick" versions with a short stinger I could see it being lousy. Hi, Reg:

I'm not too proud, or pleased, to state that the obvious escapes me from time to time.

Reg, eleison. I've never understood the syntactical usage of the second aorist passive optative in certain obscure Homeric odes, either.

I agree that the RsubR of a 1/4-wave vertical is 37 ohms.

You agree (I hope) that I can not measure field strength with a Z-bridge, or swr meter.

I'll now restate what I thought was the bleeding obvious question, in another fashion:

Given those stipulations, and that the soil k = = constant, with what procedure do I discover that the input resistance of one radial is, or may be, a common sort of value, say, 37 ohms, (or 111 ohms) using my Z-bridge, or, in a pinch, my SWR meter?

Thanks!

Merry Christmas and HNY.

Dry snow has virtually no effect on MW ground conductivity and hence
groundwave field strength. No experience at HF, though I expect that
the effect there is minimal, as well.

Dear Reg,

You are the one who stated, or implied, you could determine the earth
loss in a vertical antenna system using a hand held analyzer, not me.

It's you who are spewing out the smoke old man.

I'd wager a lot of other people who have worked with the problem all
know (or at least they should know) what is measured at the base of a
vertical does not tell you the whole story, or even half of the story.

Of course that would mean you'd have to say "I don't know" or "the
problem is complex", two phrases you haven't learned.

Dave,

You can measure the resistance presented at the common point by one or
by many radials....but that impedance does not tell you how much power
is dissipated and how much is radiated.

That's why FS measurements are necessary to prove a system works as it
is supposed to.

Hi to everyone and Happy Holidays!

I recently aquired a 4 element tribander which looks much like the Cushcraft AH4, that the previous owner says is a Telex. I don't have a manual for it and can't find one. So I downloaded the manual for the Cushcraft hoping it would be the same. However the elements on my antenna are about 2 feet longer than the manual says the Cushcraft would be.

I have the measurements from when I took the antenna down but would like to find a manual. Any help on locating one would be great. Sorry I don't even know the model number but like I said, it looks just like the Cuscraft AH4 (picture at :

http://www.cushcraft.com/amateur/hamcat.pdf).

Thanks for all the help in advance.

My brain hurts. This isn't quantum mechanics. I just read Les Moxon's (G6XN) RSGB book. Bunch of radials, any length. Or, as Les says, dig a quarter wavlength hole in the ground, stick one end of your half wave dipole in the ground - don't touch that dirt! - and bingo! You've got it.

Also, my dirt isn't a quarter wavelength of anything. Neither are my 16.335675 foot radials laying in contact with ever-changing ground conductivity characteristics except at any single point in time.

4838. Converting HV7A Mobile to Base Operation?

Newsgroup: rec.radio.amateur.antenna

From: Richard Friedman <rchrd@rchrd.com>
Message-ID: <3A465CFE.2B79602A@rchrd.com>
Source record: 173937

I'd like to use my Diamond HV7A 10/6/2/.70 multiband mobile antenna as a portable base antenna. My guess is that I'd need some radials and some kind of support mount. I'd like to mount it off a porch railing on a high pole and operate "portable" on my porch, mainly on 6/2/.7m with my new IC-706MK2G transceiver.

Before I research the matter in the antenna books, I was wondering if anyone has done something similar and might share their experience.

Thanks in advance.

Yes I believe everything the w-post has in it. I do believe that agenda driven science never has erroneous conclusions either. The Cell phone industry brought congress, turning radio's into swiss cheese so the industry could sell a fake notion of privacy, It's not to difficult to buy a few researchers and stuff their mouth with the brought and paid for script. Joe Blow with a scanner was never a threat, Big Brother defiantly is. While I was employed in electronics I would not put remote units under the table with the antenna sticking into my crotch as I many times had observed being done They know better though and would tell you so. If you want to use a cell phone, fine your decision I won't and many times I turned off paging transmitters in the same room I was working in.

When humans have learned all there is to know and have forgotten greed then maybe I will believe the latest "hot flash" but in the States public safety and health has always taken a back seat to profit and will continue to do so as long as a dumbed down population believes everything big brother and big money force feeds them.

I believe that although the energy from cell phones will not cause immediate problems there are long term effects to be taken into consideration and it you want years of tissue heating

to your head to enhance corporate profits, Fine your choice, I don't and have a hard time
with putting profit above people and lying to a largely gullible public with bad and agenda driven sciences.

Forgive my ignorance on the subject but we all should question authority figures.
I was down for a while and did not see the post you are referring to but being
politically
active and taking part in the political processes is the only way to preserve our
republic. I am not legitimizing personal attacks nor would I attempt to but I am
also
saying that the public figures mentioned are nothing less than a disgrace and
brought shame
upon our republic. I may disagree with everything someone has to say but respect
their activity

and attempt to be active.

The following is definately NOT an urban legend.

Many, many, years ago (and I do mean many) a number of the local teen agers
would go out on Halloween and tip over outhouses.

On one such occasion they discoverd that the outhouse thay had just tipped
over was occupied. (due to all the cussin' from within).

How do you get out of an outhouse when it's laying on its door? Think about
it.

The next year they went back to tip the same one over again...Only to
discover (in the dark) that the farmer had moved it three feet forward.
Watch that last step guys!

4851. X7 Antenna modeling

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-24 23:36:50 UTC
From: nospam@libero.it
Message-ID: <3a468563.14315998@News.CIS.DFN.DE>
Source record: 173949

HI All,
I have a X7 antenna by CushCraft. It's a 7 elements beam for 10-15-20 mt with a log-cell driven (4 elements), 2 reflectors and 1 director with traps.
I would like to analyze this antenna with an antenna modeling software. I tried with AO by K6STI, but the result has been very strange. Brian said me that the log-yagi needs more care in the modeling-software analysis.
The target of this job is to build the theoretical H-plane and V-plane radiation patterns of this antenna.
CushCraft did not supply any precise radiation pattern :-(
Anyone can help me, please ?

>more conventional vertical designs. In this case the fairy light wiring can
>provide useful elevated/drooping radials.

Possible improvements to the " Frac-Pinetenna":
1. Use of tinsel on drooping radials-- offset short radial length with
multitudes of mini-radials.

2. Fill water dish with salt water for "perfect ground". Albeit, short lifetime.

3. Use of metalic garland to create "helical coil" for multi-banding.

I used a setup similar to what you describe, Cecil, though I put the autotuner inside the hatchback on my little car. It worked very well for QSY inside the band. But so did a homemade L-match in the front seat with shunt L matching at the antenna. THAT lacked only an audible SWR minimum to be convenient. And it was much cheaper!

Let's see, the Ameritron AL-80B, at 1 kW output, is $1299. The AL-82, 1.5 kW, is $2295. That's 1.76 dB difference for $996, or $566 per dB. The AL-82, overall, adds 11.76 dB to a 100 watt rig, at a cost of $195 per dB. I'm sure there are lots of linears out there that come in at quite a bit less than one dB per $200. And there doesn't seem to be a lack of people buying them.

Abe,
You don't say what a BC 3000 xlt is, but I am assumming that it is a scanner which covers VHF. Radio Shack sells a discone which would probably due the job for most
of what you are after. You should set it as high as possible to get the maximum coverage from all directions. You could go for a directional antenna, but that might be defeating the purpose of the scanner. Hope this helps...

In article <3A46C028.5DA3E72E@IEEE.org>, Cecil <Cecil.A.Moore@IEEE.org> wrote:

> I do believe the highest power of two is Aleph(null).

Despite the fact that it is Christmas eve, I don't believe very much (I disbelieve a lot of things and am agnostic about a lot more). That the highest power of 2 is Aleph_sub0 is one thing I am in no doubt about -- it's definitely false.

2^n < Aleph-sub0, for any finite cardinal number n, since 2^n is then also finite, but Aleph_sub0 is not. (Aleph_sub0 is the smallest infinite cardinal number.)

Aleph_sub0 answers the question "how many natural numbers are there?". (This is essentially a definition; the answer to that question cannot be a natural number N since the set {0, 1, 2, ... , N} already has N + 1 members.)
2^Aleph_sub0 answers the question "how many real numbers are there?". Cantor proved that 2^Aleph_sub0 > Aleph_sub0, or what comes to the same thing, that there cannot be a 1:1 correspondence between the set of all natural numbers {0, 1, 2, ... } and the set of real numbers. (I will be glad to outline Cantor's proof, or a proof that there are 2^Aleph_sub0 real numbers, if anyone requests it by e-mail.)

Now the open question (and it will stay open forever) is whether

(a) 2^Aleph_sub0 = Aleph_sub1 (this is called the Continuum Hypothesis), or

(b) 2^Aleph_sub0 > Aleph 1.

The third conceivable relation, that 2^Aleph_sub0 < Aleph_sub1, cannot be true, because of Cantor's result (plus the fact that, by definition, Aleph_sub1 is the first infinite cardinal number larger than Aleph_sub0).

It has been proved that if ordinary set theory is itself consistent, appending either (a) or (b) to it (but of course, not both at once) will result in a consistent enlargement. So it will never be possible to either prove the Continuum Hypothesis (because set theory + (b) is as consistent as set theory itself) or disprove it (because set theory + (a) is as consistent as set theory itself). In other words, we'll never know.

I don't think this has anything to do with antennas, but it's neat stuff anyway. Anyone who wants references, e-mail me for them.

Now there's one thing I do believe about shortened (i.e. shorter than lambda/4) radials -- I believe they cannot be more effective than ones

which aren't shortened. How's that for going out on a limb?

David, ex-W8EZE, and retired (pure, not applied) mathematics professor

Actually it's worse than that Cecil. You not only waste energy from
the half of the dipole that can't radiate, you also have the earth
absorbing energy from the other half that is above the earth's
surface.

A nice radial system prevents both.

Hi Cecil,

Why always look at 75m performance (we prefer 80m :-))?

I use my Outbacker on 20m and up most of the time. It does work great!

I wouldn't dream of putting a bugcatcher on my car here in Europe.
Have you tried 100 Miles/Hour with a bugcatcher? I do that with the
Outbacker without problems. It makes US hams smile when I tell them
I'm cruising the German 'autobahn' at 100 M/Hr while talking to them..

It sure seems that some people are getting paid to be negative about
the Outbacker... It works great and I have the QSL's to prove it..
that's enough for me. VK, P29, JA, KL7, W6, PY, ZS, 7X from the car
can hardly be called a 'dummyload'.

Happy holidays, happy millennium.

David,

On a lark, I used mine years ago when the ground was frozen solid here in the Detroit area. The tuner's random wire position worked against the house plumbing allowed me to QSO the Rocky Mtn. states well on 75m. The tuning was not predictable or repeatable from night to night as was expected. When the thaw came a few weeks later, it became an earthworm warmer. Watch out for all the stray dogs and kids in the neighborhood, as parents get upset when you fry their offspring.

Merry Christmas,

Jim KD8GS

"David R.Gemmer",
Once upon a time, when I was still gainfully employed,
I had lots of time to play with antennas at work. Due to
my employers restrictions, what was available to play with,
and the amount of $$ I had in my pocket, some of the "make-
do" antennas were a bit unusual. A chain-link fence was
one of those that I played with.
I had/have a tuner that would 'handle' just about any-
thing. This tuner along with a set of 'jumper-cables' for
'delta' matching, made a short fence next to the station
load on 20 meters like a charm! It didn't 'talk' worth a
hoot, but was very quiet on receive. (The same set of
jumper-cables, coax, and tuner also loaded a R.R. track.)
I wouldn't recommend using a fence, but if your really
desperate enough, it'll work. One reason I wouldn't
recommend it is because if your fence is connected to your
neighbor's fence, you're going to be producing RFI all
over the neighborhood!
'Doc

Abe,
An antenna outside, and as high as you can get it, will
almost always 'beat' an indoor antenna. Height is more
important than 'size', especially for VHF/UHF.

I looked up those, and they are the thin kind, but not totally useless as they seem to at least use a decently long stinger. But the coil is tight and thin. Not good. I'm trying to think if the brand that makes the larger coil variety, but escapes me right now...But they use a bit larger coil, and about the same length stinger. I would think it would be a good bit better on 75m. Maybe even outdo the outbacker instead of losing. My homebrew version is much the same thing. I put in the bigger coil wound on pvc. I'm getting ready to make a new "super" version all band stick as soon as I get a new radio. The new one will use the same big coil, but a good bit higher on the fiberglass stick, and I'm going to use an even longer stinger. "3 ft presently". I'd like to use a 7 ft stick with the coil about a foot below the top, and about a 4-5 ft stinger. I notice lakeview sells just the type stinger I want for those. And then to top it off, I will still have the solid 3 ft extender mast that I can use below the normal antenna to raise the coil even higher. I won't be using a hat, but I predict it will still work very well on all bands 80-10. But as I said, I gotta get a new rig first. My 730 pooped out and I can't find the part so far. So I'm looking for a new one. I think a 706mk2g probably. At first I didn't like those things, but I've kinda grown to like them now. The BC to 500 mhz coverage in one dinky box is hard to pass up. I've never worked 6m fer instance. And 2m all mode would be nice to try. Aircraft, police, it's all there. Kinda handy. MK

It is Tom's smoke screen. He resorted to it when he refused
to accept that 50% efficiency is equivalent to a 3 dB loss
relative to the ideal. His antenna farm follows different
laws of physics from everbody else's.

When it failed he propagated the untruth the smoke screen
was mine.

I would have let the matter rest but unfortunately he
appears to have deceived you with his well known and often
used tactics.

Come on Tom - have your usual persistent last word. Try to
keep it brief.

A very merry Xmas.

If you remember, pass it along. There are 3-4 companies here in the states that make a "hamstick" type antenna. All are of the skinny coil variety. The Hustler antennas are the only ones that have a large coil.

I'm getting ready to make a new "super" version all
> band stick as soon as I get a new radio.

Keep us posted here. I've been pondering such an aerial for mobile use. I had been considering something like the Icom AH-4 autotuner at the base, but with much better efficiency (and lower cost) than an 8ft steel Icom whip. My antenna knowledge is not yet up to the technical details of this yet. My hope was for a reasonably efficient, frequency agile, no getting out of the car to tune, and no eyes off the road to tune, mobile antenna. I'm not asking for much :-)

How were you planning to tune your all band "Super-Stick"?

. But as I said, I gotta get a new rig first. My 730 pooped
> out and I can't find the part so far. So I'm looking for a new one. I

Source record: 173985

The used dual bander I just bought had been modified to transmit out-of-band*. I've used it on the FRS freqs but know that I could do better with a tuned antenna for those frequencies. Any suggestions as to where I can find plans for a homemade UHF rubber ducky with BNC that I could modify for these freqs?

Thanks,

Richard, KD6JAV

*Yes, I'm aware of the illegal nature of this but I figure that FRS won't be hurting anyone...

HA you think that is bad i had to replace a hairpin match on a mosley 6 meter vertical and it cost me $23 for the part and shipping and handling and all it wound up being was a piece of 1/8th inch aluminum rod bent into a U shape and a small loop bent into one end to go over a bolt
you guys dont know what poor customer service is till you deal with mosley it took me 6 weeks to get that little piece of aluminum rod and every time i called to check on it they gave me some story or another
a year or so a go i ordered a new 2 meter yagi from them it took 8 weeks to get it from them then too
atleast when i order parts from cushcraft and it takes longer than suggested it was shipped with no charge at all
i think we all forget that these customer service people may not be hams and may be new and dont know the antenna and we have been out fighting with it and we are short on paitents and tack so we come in here and blow off steam
so calm down and relax before dealing with people on the phone
also try email i have very good luck with customer service via email

Source record: 173990

Probably about the same time (mid 1960s) I was using a Globe Scout, all of 75 watts or so, and was talking with my normal friends on 15 whwn one of them suggested that my signal wasn't up to its normal strength. He then asked if I was using another antenna, perhaps the bedsprings.

I remembered the crib springs leaning against the basement wall. I got up while others were talking, fetched them, and hooked them to the antenna terminal. The Scout had a wide range tuning network and would load into almost anything. I shifted off frequency and tuned up. When they turned it back to me, I used the springs.

The guy who had made the comment came back and asked what I did, my signal was up at least 6 dB. I told him that I took his suggestion and hooked up the bedsprings. Thus some crazy ideas aren't so bad after all.

Of course within a few days, I has added a bunch of radials under my dipole and that made everything much better.

The chain link fence wouldn't have worked. My wife hates them so we've never had one. Now, having just moved, I don't have any antenna up yet, and I no longer have any crib springs handy. Oh, well...

dbd dbi hi hi hi. Hey if it works for you great if not do it your way he he.

personally in my opinion 3db loss is 50% loss of the total gain potential given what
ever math you use as it is known today. A decibel is a decibel is a decibel
its just what environment and configuration can determine gain.

So Reg looks like your on the right track in my opinion not that it matters
much to anyone but myself hi hi.

Merry Christmas

Well I've received a number of great replies about my original post, but nobody's answered my question yet. I'm wondering if anyone has the db loss figures for Radio Shack RG/8 coax? There seems to be universal agreement that it's not very good, that it's stiff, that it's shield is thin, etc. What I'm looking for is the proof in the numbers. Anybody know them? Rad Shack used to sell the thick stuff a few years ago, but I haven't seen it in their stores lately. Many thanks and 73s, John, K7JY.

I find myself wondering why you didn't buy a piece of aluminum at Home Depot or somewhere -- or use a piece of aluminum ground wire! -- and make your own? Worth not having the hassle, from what I read here about the company. Faster, too.

You could just go by the Radio Shack numbers. I see no reason to doubt them. The RG-8 has 1.9 dB loss/100 feet at 100 MHz, and 4.1 dB at 400 MHz. If you are nervous about their in-house brand, you can special order Belden 8214 or 8237 through their commercial catalog. It is interesting that the Belden 8237 has exactly the same rating as the in-house cable. I believe you can order through www.radioshack.com

It wasn't the coughing that carried him off,
but the coffin they carried him off in.

Unfortunately no spectacle will help those who will not see.

Since, it appear from the preceding posts, the measurement of soil resistance seems to be such a complex subject and the results to be so variable, what prospect is there of an antenna system that operates without the need for a good groundplane at the base of the antenna.

For a moment consider a point 500 miles away from the Antenna (no matter what is being used, bit of wet string if you like) Does the wave at that point really care about the ground resistance over which it is passing to make it the next 500 miles?

What would need to be done to duplicate those conditions at the launch point of a wave?

Happy Chritmuth and a nappy new year.

I think maybe the valor pro am has a "bigger coil" 80m stick. Also maybe
the same company that makes the carolina windoms might also make a
version like that. Not sure, but seems they did.

>
> How were you planning to tune your all band "Super-Stick"?

You would have to get out of the car for my antenna. It will be tuned
about the same as my present one, except it'll just be taller. I'll
probably use a 7 ft 10m stick as the base antenna. Or at least the
highest band stick I can get thats 7 ft tall. I'll take off windings if
needed. So the base stick will work 10m as is.
I'll add a 80 meter coil about a ft or so below the top. There will be
one tap for 40m. The stinger will be a fixed length, so the coil will be
tuned to 80m by adjusting the number of turns. There is no tap for 80m.
I don't move around much... After I get 80m tuned, I add a tap for 40m.
I'll use a jumper to put the coil on 40m, or to bypass totally for high
band use. On 30-10 meters the coil will be bypassed, and I'll have a
different stinger for each of the high bands. By the time you get up to
ten meters the stinger will be pretty short. So that gives me 80-10 with
one antenna. But I have to get out to change bands. Takes about 2 min. I
use a quick disconnect and keep a nutdriver behind the seat for quick
stinger changing. But with this system the antenna is properly tuned for
each band. No tuner used for the antenna itself, but you will need
impedance matching. I usually use a small tuner. But this antenna with
the big coil won't be mistaken for any hamstick on the air. I'll have
bugcatcher performance in an antenna that weighs very little. My present

one works real good. "8 ft total", but you know hams, never satisfied.
The new one will be a good bit more efficient on 80m. Mainly because of
the higher coil and longer stinger. With the extender , the coil will be
appx 9 ft off the deck of the car or truck. But that will only be used
when parked usually. 12 ft is tall enough for driving...g I'm counting
on the wind flex to the rear to let me clear the 13.6 ft overpasses on
the interstates. Even if I hit, no biggie. Just slaps off whatever it
hits. The 15 ft setup for camping sites etc.
>

>
> I also have the 706G and love it. It does more than I could ask of a little
> rig.

I was kinda leary of the overall HF performance, but they seemed to have
improved since the original version. The audio sounds better to me for
one thing on the newer ones. Real clear and crisp. The original version
706 was a bit pinchy. I'd actually probably would still prefer a bigger
radio, but I can't find one that does what the 706 does without paying
twice as much. I actually like the looks of the 746 better, but no UHF.
Not that I need 440, but I wanted the receiver for public service
listening, etc. But dunno, I have others of those, so probably silly to
worry about that. Just nice to have all in the one box. So many radios,
so little time. And money too....:(MK

> opinions on which one, the radio is a drake r8b.
> thanks in advance

Well, A tuner could help a bit, but you should be able to get by without
it usually. Sometimes they can help "hotten" up the reception on a band
that the mismatch is bad. But still the overall S/N ratio shouldn't
change that much. Your S meter will just read higher. Same for a preamp.
With most any modern receiver they are a waste of time, and can actually
trash out the receiver with image problems etc. I'd stay away from
those. The drake is a good radio. Adding a preamp would just trash it
out most likely. If you have a decent random wire etc, that should be
good enough unless you are shooting for some certain area or freq. But
then you would need an antenna with gain to do any better. A good test
of receivability is just listen to the rig while unplugging the antenna
when tuned to band "white" noise. If the noise increases any when you
hook the antenna up, you are ok. S/N means alot more than pumping the s
meter up. MK

.......the wire line uses an air dialectric and because of the spaceing of the wires...low loss between the two. Coax uses various dialectric materials but because the wires(the shield and the inner conductor)are very close together, the losses are higher despite the best efforts of the manufracturer. thats that

A reciever generally would like to look into a nominal 50 ohm
impedence...for the max transfer of power from the antenna to ur rx, use a
pi network consisting of an inductor and two capacitors . There are
resources on web...look for pi network antenna tuners and "make" it.

This would be true if the power into the monopole is half the power into the dipole, for example, if the author excited both antennas with the same current rather than the same power. Otherwise, this is definitely a text and author to avoid.

And guess what -- if you put three times as much power into the monopole as you do into the dipole, the monopole radiates three times the power that the dipole does. Amazing, huh?

dc6022@my-deja.com wrote:

> Does any one know how to measure or evaluate the Q value of capacitor
> (12pF; NPO) which is used at 1.5GHz ckt.?

One method:

Use a high-Q resonator, preferably a cavity resonator, with *extremely*
small coupling to the generator and load. Determine Qr with a 12 pF
very-high-Q air capacitor, using the 3 dB frequency response method and
using a frequency counter and an accurate spectrum analyzer. Then replace
the reference capacitor with the test capacitor and get a new Qt value.
The Qtc of the test capacitor itself is

1/Qtc = 1/Qt - 1/Qr

The test capacitor may not be what you think it is at 1.5 GHz, because of
internal and lead wire inductances (it should preferably be a chip cap).
If the cavity does not resonate close to 1.5 GHz it probably has
considerable inductance. Compare low freq C and 1.5GHz C to find this
inductance.

This test setup is not a simple exercise. Unless you *really* want to do
it, ask to see the vendor's detailed spec sheet.

Several years back, about the time RG-8X came out Radio Shack had some cable advertised and there was a magazine artical on some of their coax. The stuff did not meet the loss they advertised. Can't remember which magazine it was in but probably was in either QST or 73 Magazine. Also there has been several articals and comments about their lossy coax adapters.

Unlike an antenna tuner not helping out on transmitt losses in the coax, it will help out some in the receiver. This is because you are actually matching the receiver to the line and that is the load. Depending on the band and swr looking back to the receiver from the antenna and cable loss it could help alot on the S/N ratio.

It appears to be the same current. It says the E and H fields for
a monopole are identical to 1/2 of a dipole.

Source record: 174009

Dear Dave,

Tom knows how to measure the input resistance of radials as
well as most folk. He asked the question rhetorically, as a
diversionary tactic, part of the unsuccessful smoke screen.
It was not worthy of an answer.

But the answer can surely be found in ARRL publications.
Sorry I don't have the full up-to-date set or the time to
wade through them to provide you with the exact
reference(s). The answer very likely can also be found in
Spanish, French, German, Russian, Japanese, Chinese and
Indian publications.

So to obtain the input resistance of one or a number of
radials associated with a 1/4-wave vertical antenna,
carefully follow these instructions :-

(1) Using alligator clips connect your antenna analyser
between the bottom end of the antenna and the near end of
the radial.

(2) Switch on the analyser.

(3) Vary frequency for minimim impedance reading at 1/4-wave
resosnance.

(4) Subtract 37 ohms from the minimum impedance reading and
there you have it.

(5) Switch off the analyser to save batteries. They are
power hogs. But the best things since sliced bread.

With the dynamic range a good commercial receiver has, that is
not very important. My IC-706 only requires 0.16 uV for 10dB S/N.

How to you tune the antenna? Do you have a motor on the vacuum cap, or do
you have some preset positions for each band?

Curt Breneman
RPI Chemistry
KC2EBP

Curt: for now, a single vacuum cap setting accommodates 30, 20, and 12 while
for 40 I'd remove the cap and add the L in series.

If I want to use the system on 17, 15, and 10 I remove the vacuum cap and
insert a variable mesh type capacitor.

Not very elegant but it works...of course, living in Charleston, S.C.
helps - if I resided at my old QTH back in Wisconsin we wouldn't be talking
about switching 'nuthin around this time of the year...LOL!

There is a fella out in the midwest who advertises a switcheable capacitor
box, in QST. I called him some months back and found out he's got a weather
proofed version from 3 up to 200+ mfd and I've been considering buying that
and trying it. Would be great to have set switch positions I could go out
and change for the different bands...believe the cost was around $45.00.

Regards, Jim R.

4915. Hams Helping SWLs

Newsgroup: rec.radio.amateur.antenna

I see quite a few posts here from SWLs requesting assistance from hams about antennas and I'm glad to see they are getting it. Although there is a news group for SWLs, the quality of response here appears to be a bit sharper and a touch more technical. If an SWL gets the assistance he needs, his view of the ham group improves and he/she is more likely to look into ham radio.

I started out as an SWL, got my ham license, then decided I prefer SWLing. I still consider ham radio as a great potential hobby and I use this group as my main source for newsgroup type information.

Lets keep the friendly attitude between hams and SWLs rolling on.

Thanks.

What is your reason for wanting the actual particulars on the RS cable?? Doesn't make sense to me. The stuff is well known to be crap so you don't use it. End of where I come from.
>
The only way you'll get the right answer is to buy 100 feet of the stuff and pump RF thru it into a dummy load with Bird wattmeters on both ends of the cable.

Dear Reg:

As one who does not have a pecuniary interest in ARRL publications I would like to weigh in on the side of W7EL. I know some of those who write for the various ARRL publications and they do possess the appropriate technical credentials and do quality work. The worst error I have found in an ARRL publication was a square root sign that did not enclose enough of an equation, and this was obviously a type-setting error.

Going further back, much of the information in the ARRL Antenna Book has its roots in the works of Messrs Beverage, Brown (phased verticals), Kraus, and Lawson (Yagis), much of which originally appeared in the Proceedings of the IRE or in Lawson's case was published in his text on Yagis. (Lawson also wrote one of the volumes of the classic MIT Radiation Laboratories Series. He later became head of R&D for a small company called General Electric.)

Best Wishes,

Bob, N1RC

The people who comprise the IEEE committee that sets these standards are drawn from a wide range of researchers, industry and user groups (such as ARRL). There are very clear dangers to high levels of RF that have been documented by good science -- the levels of the standard are set based on what has been demonstrated by good science. Groups like the American Medical Association and American Physical Society have made recent announcements that RF exposure *at the level of the standard* has not been demonstrated to cauase cancer. Why would the AMA "lie?"

The threshold is based on a specific absorbtion rate of 4 W/kg of body mass. It is at this level that various studies show unwanted health effect. (None of these effects have been tied in to long-term health hazards; they are indeed short-term and thermal in nature.) From that level, the standards committee added safety factors -- 1/10 for controlled/occupational exposure and 1/50 for uncontrolled/general-public exposure.

Let me put that into terms that most people can easily visualize. An absorbtion rate of 4 W/kg would be attained if someone locked themselves into a very small closet with a 500 W heat source (let's use a light bulb -- its radiation is electromagnetic and would ultimately be absorbed as heat in this closed system). I can see how a 500-watt heat source in a small closet would very soon overheat the occupant to the point of causing temporary unwanted health effects. Now, let's expose him at the controlled exposure level by replacing the 500-watt bulb with a 50-watt bulb. Okay, on a hot day, this may add a bit of thermal load, but not enough to be dangerous to most people. Next, we will replace the 50-watt bulb with a 5-watt nightlight, to exposure the occupant at the uncontrolled level.

I trust this will help put the levels involved into the correct perspective.

I would be concerned about safety if it was at all possible someone could
contact the antenna.

Any corrosion or dissimilar metal junctions could arc or become non-linear,
generating harmonics or IMD.

You got that right. I've noticed some weird things things on 160m lately in that dept. It's real easy to get a bad connection to act as a rectifier, and it will spew AM broadcast garbage all across the band. It's like a distorted AM BC birdy every ten kc. I'm having that problem here, and not sure whats causing it. It's intermitant and sometimes will just flat instantly disappear, so I think a bad connection somewhere around here. It may have something to do with all the dang xmas lights that are plastered all over the house right now. They are effecting my 160 dipole and acting like a reflector a bit. I'll be glad to get that stuff off the house. I'm also tied into a chain link fence, and that may well be a problem also. I need to go out and unhook from it and see what happens. All this mess started recently. My receiver used to be pretty quiet as far as junk. Somethings goofy around here...But I just checked right now, and quiet as a mouse. Go figure. When I get it, it's on either antenna, so not an antenna problem per say. Something else in the area. MK

Roy Lewallen wrote:
"This would be true if the power into the monopole is half the power into the dipole, for example, if the author excited both antennas with the same current rather than the same power."

Cecil had quoted Edminister as saying, "As the monopole radiates power only in the region above the conducting plane, the total radiated power is one-half that corresponding to the dipole."

Edminister must assume that half of a vertical dipole is hidden below the earth in such a way that its impedance and power input are not affected but half the radiation is lost to free-space.

The opposite assumption is usually made. The monopole is assumed installed over perfectly conducting and reflecting earth. Power input to the monopole is made the same as to a dipole in space.

As the same power feeds the monopole, radiating in only one hemisphere, as would feed a dipole in a free-space spherical pattern, 3 db gain is credited to the monopole.

The math is OK. Power is current squared times the resistance. R for the dipole is about 74 ohms. For the monopole, R is about 37 ohms (half the dipole value). In the monopole the current is the square root of two (1.414) times the current into the dipole for the same radiated power. Twice the value for the current squared times half the resistance obviously produces the same calculated power. Nothing complicated and no magic.

Best regards, Richard Harrison, KB5WZI

Bill S offered some good words of wisdom on this. I'd agree, it ain't an easy exercise. Extending his idea of comparative measurements, you might put it on a (very good) network analyzer and _compare_ it with a known cap. The capacitive reactance is pretty low, only about 9 ohms, so even a very tiny amount of series resistance will lower the measured Q. Making reliable connections with low resistance is very difficult, so you might make the measurement several times and see different numbers each time, just because the resistance is different! If you can solder it into a test fixture (circuit), that could help a lot. (Our component test fixtures pretty much always use a four-wire connection for this reason.) My suspicion is that the losses will be dominated by series resistance, and actual in-circuit losses likely by the resistances external to the cap itself.

Cheers,
Tom

Well just for fun I did some calculations at various frequencies for a system composed of a 1 inch long UHF barrel connector, with a PL-259 plug on each end. The dielectric length of the PL-259 plugs I measured was 0.25 inches, and the barrel connector was 1 inch long. Each plug, and the barrel adapter, were treated as a transmission line. The three "transmission" lines were cascaded in series, a PL-259 plug on each end of the barrel adapter. A "perfect" 50 ohm load was assumed connected to one PL-259 plug, and the SWR meter was connected at the end of the other PL-259 plug. The input impedance for each "transmission" line was calculated starting with the perfect 50 ohm load, and then used as the load impedance for the next "transmission" line. The length of the "transmission" lines were converted to the equivalent wavelength based on the test frequency, and VF of the line. The loss less transmission line equation was used for all the calculations below.

The dielectric constants I used were pulled from a copy of the book "Reference Data for Radio Engineers" published by ITT.

Er=1.0 (air)
Er=2.1 (Teflon up to 3 GHz)
Er=4.6 (Phenol with 65% mica fill at 1 MHz)
Er=4.04 (Phenol with 65% mica fill at 100 MHz)

Er=3.57 (Phenol with 65% mica fill at 3.57 GHz)

VF=1/sqrt(Er) was assumed too.

I did find references, on the Amphenol Connectors web site, where they use a mica filled dielectric in some of the UHF connectors they manufacture. You should be able to look up specific connectors, then look under the specifications, to see what types dielectric materials you can get them in. The dimensions I measured on a barrel connector I took apart were; adapter pin OD equals 0.217 inches, and the adapter shell ID equals 0.47 inches.

(Zadapter in ohms with an Er of adapter of)
(1.0 2.1 4.0)

46.37 31.998 23.185 (ohms)

The calculations were made at 430 MHz, 222 MHz, 144 MHz, 50 MHz, and 28 MHz. The dielectric constant of the material in the PL-259 plugs was assumed to be 1.0 (air), for this test.

(Freq) (SWR with an Er of adapter)
(MHz) (1.0 2.1 4.0)

430 1.052 1.207 1.469
222 1.027 1.108 1.253
144 1.017 1.07 1.162
50 1.006 1.024 1.054
28 1.003 1.013 1.03

Now repeating the calculations at 430 MHz, 222 MHz, 144 MHz, 50 MHz, and 28 MHz. The dielectric constant of the material in the PL-259 plugs was assumed to be 2.1 (Teflon), for this test.

(Freq) (SWR with an Er of adapter)
(MHz) (1.0 2.1 4.0)

430 1.253 1.548 2.047
222 1.125 1.263 1.498
144 1.079 1.165 1.307
50 1.027 1.055 1.099
28 1.015 1.03 1.054

Now finaly repeating the calculations at 430 MHz, 222 MHz, 144 MHz, 50 MHz, and 28 MHz. The dielectric constant of the material in the PL-259 plugs was assumed to be 4.0 (Phenol with 65% mica filled), for this test.

(Freq) (SWR with an Er of adapter)
(MHz) (1.0 2.1 4.0)

430 1.489 1.97 2.794
222 1.231 1.439 1.785
144 1.145 1.269 1.467
50 1.048 1.087 1.144
28 1.027 1.048 1.079

As you can see the mix of different dielectric types can result in widely varying SWR's. It would appear that even Teflon dielectric for 70 cm use may be no good with UHF type connectors, unless you have a perfect 50 ohm load. The results for 2m, using Teflon connectors, however look aceptable. If you take the time to examine the V/UHF type of connectors used on high quality SWR meters, power meters, and antenna mounts, you will find the manufacturers use a "web" dielectric type of design. This is to get the impedance bump of the UHF connector as close to 50 ohms as they can get. They can do this because the "web" dielectric design is mostly air.

Measuring SWR at V/UHF has to be done with care. If the SWR meter is at the rig end of the line, and the splice point some distance away, the SWR will look lower because some of the reflected power is lost in the coax cable. So with reduced reflected power the SWR meter will show a better SWR that what you really have.

If anyone wishes I have the Mathcad worksheet I used, which I can E-mail for further calculations. You will have to let me know what version of Mathcad you have since I have to save the worksheet in the format specific for a given version, such as 2K, 8, 7, or 6 only.

>that's enough for me. VK, P29, JA, KL7, W6, PY, ZS, 7X from the car
>can hardly be called a 'dummyload'.

I'm sure that at least a few bugcatchers in the states have successfully withstood the rigors of 160KPH travel, probably not legally but withstand them none the less. I do note that many successfully manage 70 or 75 mph legal travel in places like Texas and Montana. I suspect that a 15 cm diameter bugcatcher on a magmount isn't a good idea, but a normal mount, and grounding to the auto frame probably is more effective on 75 meters and 40 meters than an outbacker. XYL and other appearance issues may make the outbacker a better choice, but just for either mounting considerations or performance issues, a screwdriver and/or bugcatcher is probably no more difficult to mount or use. Low bridges, awnings and other factors might make an outbacker more likely to survive, but for radiating and receiving, the screwdrives and bugcatchers seem to work better.

It's also been my experience that almost any antenna will work mobile, but consistency of performance seems to require more than an outbacker, no matter how durable they are. I'm glad you like your outbacker, and you're happy with it, I wouldn't be, and I've played with them. They're fine on 10 meters, even on 15 meters, but on 75 meters, or 40 meters, they're just not acceptable to me.

Large loops (quad elements) radiate well at the overtone resonances: these are not exactly at the 2;1, 3:1 etc harmonics, but are offset a little. The pattern changes, though. For the 2nd, 4th etc overtone there is no radiation at exactly right angles to the loop plane. If you use good transmission line and an antenna tuner, the loop radiates well for all frequencies from about 1/2 resonance to the point line loss becomes dominant. And if you make a loop with large enough conductor (or a large cage), the loop feed is around 100 ohms with almost no reactance for frequencies from about 1.5 times resonance up.

Very inapropriate analogy. Lightbulb in a closet is not equivalent to RF
exposure and transparency of human body to HF frequencies.
Lets ban all RF and be 100% "safe"!!!

We have unfounded RF "standards" and you are already "explaining" and defending
it. What's next? Don't breathe air?

Mark, Thanks for the details. I'll study and consider this further.

FYI: I have seen a new hamstick named Iron Horse (or something like that)
It has the standard male 3/8 thread at the bottom (for the base mount) and a
3/8 female at the top, to allow the pre-adjusted stinger assembly to be
screwed into the top of the fiberglass base section. A real nice touch. The
other option it may allow is two of the base sections to be screwed together
for 8ft total of fiberglass. Add your own monster coil and a 3-4 foot
stinger to the top and you may have a pretty decent long mobile whip (11-12
ft) with the capability to easily unscrew into 4 foot long sections for
storage or transport.

I don't really want to be having to defend suppliers, but Radio Shack
also sells Belden RG-8U (8214 & 8237) under part numbers 910-1578 and
910-1579. Belden is a very respected name in coax.

Hello Yuri,

Last week you stated that you had a 5 year prison sentence hanging over your head from some time back. When asked what you were convicted of, you went into a tirade of personal attack (you never answered the question), finally ending with a statement that you had left the NG and would not return for "several months".

And here you are...

This behavior is a serious problem. If it continues, at least against me as an individual, it will lead to civil AND criminal charges against you. I am stating this here because you are already publicly going against what you said you would do, and I see another one of your outbursts, filled with innuendo and attack, emerging here.

If this occurs, given your previous statements, it will be used as evidence in the claims which will be brought against you, should you not attain a civil attitude and presentation which is free of malicious libel and attack. If used, it will be one of several pieces of historical and now ongoing public posts to

show your pattern.

This NG is a public forum with defined norms of behavior. Please stay within them. This will be the last opportunity you will have to hear this from me.

Cordially,

Nathan Cohen, Ph.D.

It's just a full wave loop so go buy some wire, a few insulators and enough open wire to reach your turner. You'll have a better antenna. Don't fall for their hype.

A 3 element tribander 20-15-10 at 35 feet will probably be a better compromise than anything else at that height. Several dB gain better than a dipole at that height. Front to back and front to side ratios of 20 and 10 dB. Rotatable directivity.

Very easy to buy and install with a low cost rotator and a low cost tower. Good common sense for modest operatimg goals.

The tower will support an inverted V for 40 and 80.

And a giraffe, as we all know, is a horse designed by a committee.

>Can you provide any examples of ARRL material that is as "scare-monger" oriented as this post implies?<

Which "ARRL"? There are two. The ham "organization" of course isn't for profit and is tax exempt. ARRL Publications, the "material generator", on the other hand, IS very much for profit--a bit of duplicity often overlooked. So, while the League's "educational" efforts may not engauge in outright scare-mongering per se, they're certainly not above reveling in the opportunity for some baldfaced marketeering! They have the weapon, the motive, and the opportunity!

Yep, 35' is about 1/2WL on 20m. It will do a fine job and actually
give you a larger footprint than a 100' tower.

I have been reading about the LOOP SKYWIRE..best kept secret in ham radio according to some user(s)..I wonder if a small loop..17 or 18 ft per side(fundamental freq approx 14 mhz) would work on harmonics up to and including 6 meters. This antenna would be temporary for 6 months or so until I install my 48 ft tower and hopefully..a good directive beam. 73 Earl VE3AB

>
> What does he really say Cecil?

"17.7 Monopole Antenna A conductor of length L/2 normal to an infinite
conducting plane forms a monopole antenna. When fed at the base the
resulting E and H fields are identical to the dipole's. This is evident
when the image of the monopole is positioned below the conducting plane
as shown in Fig. 17-7. As the monopole radiates power only in the region
above the conducting plane, the total radiated power is one-half that of
the corresponding dipole. From R(rad)=2P(rad)/I^2(0) it follows that the
radiation resistance is one-half the value for the dipole. Thus, for L/2=
WL/4 (quarter-wave monopole), R(rad)=36.5 ohms."

4952. 10 meter antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-27 01:03:41 UTC
From: Jean Pierre Magnan <incendie@softhome.net>
Message-ID: <B66EAA1D.EBF%incendie@softhome.net>
Source record: 173900

I am planning on putting a 10 meter antenna up. I am on a thight budget.

1st scenario: I use a friend's MFJ-16010 random length wire tuner. I could string a 150-200 feet insulated wire in the trees around the house. This would cost me next to nothing. The only problem is that I don't have the manual for the tuner so how should I attach the long wire to the tuner. There is no lug at the back of the tuner, only an SO-239 connector.

2nd scenario: I could get a Cushcraft TEN-3 beam for about 130$ (CAN). I figure I could use my TV rotor to rotate it. It'll be at around 25 feet above ground until I can get my tower up.

3rd scenario: Something like a Carolina windom or a dipole between 2 trees near the shack. It would probably require an antenna tuner (other then the MFj-16010 though).

Once again I am seeking your advice to help me find a solution to my antenna problem. I welcome any comments.

I must say that money wise I (and most probably my XYL too) would prefer to go with the first scenario. I will definitely have to work out the details regarding how to connect te long wire and the ground to the tuner but I bet that it should not be to much of a problem.

Stay safe !

When ten is open you can work do a lot with a dipole much more with a beam. I don't see what you will gain with a random wire and a tuner. If you want something cheap and works quite fine do a search on a wire half-square antenna. It is two 1/4 wave length wires hanging off of a 1/2 wavelength. This will work very well for very cheap and hangs between trees and such real nice. Cost you 1/2 wave length more in wire than a dipole. On 10 meters you can afford it! I have used a half-square on 10, 15 and 20 and was quite pleased. I plan on erecting one to cover 17 and 12 meters.

You won't usually open the band with a small beam at 35 feet but you'll work
'em. Many claim that quads are better than tribanders at heights below 40 feet.

Tom, I mounted a 10-15-20 meter tri-bander on a 8 ft Martin roof tower. I it might be 30 ft high, maybe. It is so many times better than my dipole and vees and verticals. I almost always work what I hear on 100 watts if I can out smart the large cannons. I have moved up in the ranking in the contest I participate in and actually got a section first place in the 1999 10 meter dx contest. Never came close with a dipole or vertical during the previous solar peak. Do it you will be happy you did and as some bright individual mentioned you can hang a 40 and or 80 meter wire.

-----As with so many things, it depends. With many co-located
transmitters and receivers, the IM produced can be the limiting
factor. I recall that on a flat-top, solid line had to be used to
overcome IM produced in the braided coax. It was thought that the
problem was in the radios, but during a refit with extra filtering in
the radio (but still using coax to the load) the IM would not abate
independently of the filtering! 73 Mac N8TT
P.S. I intended to say Ag (silver) not Au (gold) for RG214.

Eric,

If you mounted your antenna to a metal railing, I gather it is a condo
or apartment installation, and not for your car.

Late this fall I wanted to put up a 20M antenna before the Chicago
winter arrived. I used two Valor Pro-Am 20-meter mobile whips, a $13.00
Transel TDAK dipole mount (http://www.transeltech.com/) up about 35
feet with a $30.00 MFJ hamfest tuner.

With this modest antenna and 100 watts I worked central and northern
Europe, Japan, South America, South Shetland Islands, South Africa,
Australia, etc. Most stateside contacts get good reports with 10 or 50
watts. It is keeping me busy this winter.

That's true, but not if you ask for one of the part numbers I gave
below. I will also say that special ordering at RS is amazingly fast.
Delivered right to your door. Being an informed consumer doesn't
really take that much effort. I'm not saying you should buy your coax
at RS, just that you CAN buy quality coax at RS if you know what to
ask for. I buy mine from http://www.cablexperts.com/

Greetings,

Does anyone know of any commercially made product(s) for feeding ladder line (or any type of "twin" lead) into a house without drilling holes in the window and/or frame? I envision something where the window would be slid open a few inches, the gadget placed into the opening, then the window slid down, "locked" in place with a sturdy dowel wedged in place to prevent opening from the outside. I guess I could "homebrew" such a gadget but I wonder if such a thing already exists? Comments?

> long you don't disturb the solder while it is hardening.

Good electronic solder has 2% antimony to keep the joints bright.
i.e. 60/40 is really 59/39/2

If you hold the iron on for *too long* then you will boil off the antimony
and the joint goes dull.

The secret of a good joint is:

Support both parts of the materials to be joined so that they will readily
remain in that position without any assistance,

wipe the iron clean and bright on a wet sponge, if it cools listen for the
click of the thermostic control,

apply it to both halves of the material to be joined and bring them up to a
temperature (the temperature voltage anolog) just above the melting point of
the solder to be used.
Again listening for the click can help. This can be assured with a curie
point tip of the correct number, usually a number 6 or 7 and of the correct
shape to limit the heat flow (i.e the heat current analog),

and then having cut the dead bit of solder off (1/4") that has no resin
flux in it (boiled off by the previous joint),

apply the solder to the WORK and not to the iron.
NEVER carry solder to the joint on the iron, by the time it gets there the
antimony will have boiled off.

Once the solder flows remove the iron.

The resulting joint should suck a nice meniscus of solder around the the
materials being joined.

```
I I
___)I(___,I,___ Imagine the tops of the brackets are not there
)I( 'I' Imagine the bottoms of the brackets are not there
I I
```

There should be NO surplus of solder.
If the solder hasn't pulled into a meniscus then there is a good chance that

it is not a good joint. A sound mechanical joint will have the best electrical properties. Usual reason for bad joint is failing to clean the materials BEFORE you start to apply solder.
Working from the junk box particular care to cleaning is worth the effort.

Practice makes perfect.
To do the best joints it takes about a week of practice to get back onto good form.

Rich,

You've got the right idea. For years, I've just put a piece of
some sort of insulation on each side of the ladder line where
it passed through the usual "slide-by" aluminum window frame.
Then I seal the open gap with good old duct tape.

I've run a full KW through this arrangement with no ill affects.
(I do it now with a full 5 watts QRP, and it works fine.)

Don't forget the dowel. I did once, and was burglarized!

4966. Re: QUESTION: Can shortened radials be effective?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-27 05:32:15 UTC
From: richardharrison@webtv.net
Message-ID: <28966-3A497EDF-67@storefull-117.iap.bryant.webtv.net>
Source record: 173916

Cecil enlarged upon the earlier quotation, adding:
"---From Rrad = 2Prad / current squared, it follows that the radiation resistance is one-half the value for the dipole.---"

This equation can be restated as:
P = I squared times R/2
P would be the monopole power
R would be the radiation resistance of the dipole
R/2 would be the monopole resistance
I is the dipole current

For the equation to be true, the current (I) must be the same for the dipole and for the monopole.

Best regards, Richard Harrison, KB5WZI

If, in general, consumers were actually informed RS woulda gone belly-up years ago. Lotta good, fast cable sources, my own favorite is The Wireman. As far as quick delivery is concerned I'm in an odd situation: There is a small but quite good ham gear store just over the border in Delaware from here which is owned by a YL we call "The Candy Lady". I can call her any time before 4pm and order what I need, she lives just around the corner from me, I can pick it up by 6pm. No FedEx or UPS charges. Heh.

Since the size of windows varies all over the place, most of us just
roll our own. I have a piece of 1/4 inch thick plexiglas that fits in
at the bottom of the hamshack window.

The Hexbeam is coming up a real winner when space and weight are big
issues. The hexbeam is simply a folded-up very close spaced yagi.
Real-world forward gain is modest at best but the F/Bs can be very
high.Quite possibly the biggest fully commercialized and user-tested
bang-for-the-square-foot or pound out there.

Tom,

I got your point. The chip cap. supplier books the test frequency as
1MHz low. I was trying to measure the Q at LCR meter(w/ 4wire test
fixture) and impedance analyzer. However, no matter how I calibrate
the instruments, the Q read out is still negative at 1MHz. The cause
might be what you concern about. Any suggestion to get the correct
readout?

Most interesting. In my several decades as an engineer and technician (including military), I've never encountered solder containing antimony. A quick look at a Newark catalog does show some 95Sn/5Sb alloys as lead free solder for HVAC and food service equipment, but nothing like you're describing. And that one 95/5 alloy is the only one containing antimony shown on my Kester "Solder Alloys Guide". (Interestingly, there's a lot of information on the Kester web site about lead free solders, along with a statement that they feel elimination of lead containing solder is inevitable.)

Are the solder vendors adding the antimony without telling anyone (which I seriously doubt), or is this some special alloy you can buy? Is there a eutectic combination with tin and lead? If so, what percentages of tin and lead are required?

Roy Lewallen

> . . .

Many years ago, I was surprised to find an SO-239 antenna connector on a surplus commercial 450 MHz transceiver. (As I recall, it was a Motorola "twin V" -- originally used in a taxi or similar service.) But it's apparent how they got away with it. The transmitter output matching network could easily be adjusted to match whatever impedance was presented by the combination of the connector and 50 ohm load, to effect maximum power transfer. The connector wouldn't have any effect on the transmission line SWR, being at the transmitter end. Similarly, the receiver input impedance could be adjusted so that the load seen by the antenna when receiving was 50 ohms, again resulting in a 1:1 transmission line SWR and proper load for the antenna. So no harm was done.

If there was a connector at the antenna and the antenna had some means of matching (a gamma match for example), it could be adjusted to compensate for the connector. Again, the transmission line would have a 1:1 SWR and everything would be properly matched.

The trick is to have the connector close to the point where a compensating matching network can be placed (or at a point where a network already is -- a network that can be adjusted or designed to compensate for the connector). If you can do that, you can use pretty badly mismatched connectors or other components with very little performance degradation. (If the match is really gross, you can incur loss or narrowbandedness from the matching network.) The farther apart the matching network and mismatched component, the more narrowbanded the compensation. You'll also have an elevated SWR on the transmission line between them, which will result in added loss if the line loss is

significant to begin with.

So whether a mismatched connector or other component is a problem depends largely on whether you have a compensating network, and where it is relative to the connector or other component.

Thanks for the quantitative data!

Source record: 173832

The impedance of twin, figure-of-eight, flexible, multi-strand cable, such as may be used for speaker cable, or for small 110/230 volt appliances, is approx 125 - 145 ohms. Zo is relatively independent of wire gauge because diameter/wire spacing ratio remains fairly constant.

Insulation is pvc or similar which has a higher dielectric loss-factor than RF-grade polyethylene due to chemical imperfections, color pigments etc.

But dielectric loss is very low at HF on all types of cable. Loss is mainly due to conductor resistance. So 20 awg or 18 awg twin zip-cord has a lower loss (when dry) than small-bore 50-ohm coax simply because its Zo is 3-times higher for similar gauge conductors.

Archer 18-gauge twin speaker wire, stranded, polarised, brown pvc, has Zo = 140 ohms, attenuation = 0.5dB per 100 feet at 10 MHz, and a velocity factor = 0.70 Also use it for choke baluns wound on ferrite rings or rods.

A British twin-and-earth 18gauge solid conductor cable for 230volt domestic lighting cable has Zo = 116 ohms, VF = 0.55 and attenuation = 0.9 dB / 100-feet at 2 MHz.

Twin cable with both wires close together, embedded in a thick circular sheath, has an impedance of roughly 75 ohms. Use it at HF only when it is polyethylene-insulated and manufactured for HF use.

I've been using the HX-5B Hexbeam since the Spring of this past year. Forward gain appears to be very good on all bands, f/b ratio is best in the CW portion of each band, deteriorating the higher you go on the band. I'm very satisfied with the antenna. Construction is excellent and it has withstood high winds very well. In a recent DX contest, I worked 103 countries in 32 zones on 10 meters in just over 5 hours, while running an AL-80B amp to the Hexbeam. When you're comparing it to other antennas, be sure to compare it to other FIVE BAND antennas. When comparing cost, compare the cost of the entire installation, not just the antenna. Here's a link to my website with more info and photos on the antenna. http://home.sprintmail.com/~sentek/hexpage1.htm .

If you have any further questions, send me a real email address and I'd be happy to answer them.

Never seen such a gadget, possibly because windows come in so many
widths.

A 2"x4" from the local lumber yard, cut to the width of the window,
works well. A little piece of insulation nailed to the top of the
board will cut out the drafts. You can then paint it or not, drill any
manner of holes in it...

Hello Gary, welcome back from wherever you've been.

Measurement of soil resistance is not difficult. The problem
is how to use, or more often abuse the figures when you've
got 'em.

The difference in received signal strength on a two-hop path
when (1), the midpoint reflection is from a calm north
Atlantic ocean, and (2) the midpoint reflection is a
landmass such as north America, is crudely 6 dB. (Reflection
coefficient = 0.5 and depends on elevation angle)

To make up the difference at the launch-point would require
transmitter power to be increased 4 times. Increasing the
nimber of radials from 60 to the regulation 120 would not
make a scrap of difference.

Getting antimony into solution in the first place is a bit of a chore, but once there, the melting point of the alloy is not much affected.

Don't recall seeing any solder with antimony in it, but lineotype (SP?) metal had quite a bit by design (makes the alloy harder and molds "crisper"). And a soldering iron will melt it.

Bullet casters prefer lead alloys with a bit of antimony for the same reasons.

Ever hear of silver solder? You can't melt pure silver with any ordinary soldering iron either, but once alloyed with lead and/or tin....

Why is it then most (all) commercial HF sites use 120 radials? If they can get 'good enough' performance with less, why don't they use less? I assume they all like to save money and more radials cost more money, especially in a commercial enviornment? I'm not trying to be a smart 'ass' here, I am genuinely interested.. I am getting the impression that 'more radials' are a waste of time, especially for an amateur setup? Is this correct..?

Use just one small hole. Bring both insulated wires through
the single hole close together for an inch or so. The only
noticeable effect might be a change in the setting of a
tuner capacitor of 1 pF. Drill hole through glass or metal.

Gary7SLL wrote:
"Does the wave at that point really care about the ground resistance over which it is passing to make it the next 500 miles?"

The wave is a sky-wave, and it may be attenuated by ionization it penetrates. But, a ray is affected by ground only when it strikes ground. This happens on take-off and landing. It can also happen at intermediate points if there are multiple hops for the sky-wave.

Current in a wire is encircled by a magnetic field and radiates an electric field perpendicular to the wire.

An unattenuated ray traveling the wrong direction could be turned around by a perfect reflection from the ground, or something else, and if that happens, the reflected ray could be exactly constructively phased with a wave traveling the desired direction. So, two coincident rays could have double the impact of a single ray.

More reflections from more surfaces could do more, but from a plain earth surface only one reflection is likely to be helpful in any particular direction. Radials are used with vertical antennas to reduce reflection loss.

A dipole in free-space has r-f displacement current. This is like the current in a capacitor and flows through space without wires. Displacement current flows because there is an alternating potential difference between parts of the dipole. Displacement current creates a magnetic field just as current through a wire does. The displacement current flows mainly between parts of the dipole, and because it is in free-space without clutter, there isn`t much loss.

The ground-mounted vertical also has r-f displacement current, but the ground must be one plate of the capacitor this implies, unless it is replaced by something with less loss. Copper radials are usually supplied to have less loss than soil.

Most displacement current involve a soil area near the base of the vertical. Less than a wavelength from the antenna base reactive displacement current drops to nearly zero.

Buried radials try to make the soil conductive.

Elevated radials try to shield the soil from displacement current and replace the soil as a conductor.

Best regards, Richard Harrison, KB5WZI

hello!

Have done some tests some years ago with power line / speaker line.

for a 30 meters long piece :

3 MHz 0.7 dB
7 MHz 1.8 dB
10 MHz 2.5 dB
14 MHz 4.0 dB
21 MHz 5.5 dB
30 MHz 7.5 dB

It was a two colors red / black with twisted multi-wires of good diameter (12 mm perhaps without the insulated part). Something as the DC cord for a VHF 50 Watts Rig.

So, only usable in /P, for a short line and ... on 80 meters band. Or to get a very fine ROS on ten !! :-)

Hi Jerry,

Commercial sites use 120 radials partically because they want to safe
rather than soryy. Actually, 60 radials are enough to be at the point
where adding more makes little difference.

Reg's intentions are certainly good, but he greatly oversimplifies
some problems to the point where his answers are meaningless. The
truth is:

1.) The resistance we might "measure" at the feedpoint of an antenna
is often a "modification" of the loss resistances and radiation
resistance of the system.

2.) That "resistance", even if we sort out the part useful radiation
is from, NEVER includes all the loss resistances associated with an
antenna near earth. The resistance can be all over the place
regardless of loss.

3.) A measurement at DC is (at best unreliable and more likely)
meaningless at RF, since skin depths and impedances (as well as
losses) are totally different.

That's why BC stations always use the slope of attenuation with
distance to determine average effective soil losses, and why they
always use FS measueremnt to determine efficiency. Any BC engineer in
his right mind would laugh his fanny off or sigh with disgust at a
suggestion base resistance or a "resistance" test at some frequency
far removed from the operating frequency is meanigful.

When one guy sits back and says the entire rest of the world and how
they do things is wrong, it pays to look a bit deeper in his claims.
While well intentioned, the advice the rest of the world is wrong is
probably not accurate.

I never consider subjective data for anything more than it is, and
opinion.

I'd be interested in published measurements of just how bad IMD can
be.

As a perrsonal aside, I find it EXTEREMELY unlikely that the cable was
a major contributor (let alone a noticable contributor) to IMD in a
system like that if the other cable was not defective. Often times
site people accidentally "fix" a problem (I've seen this hundreds of
times over the years) by blindly changing things and disturbing
everything in the system, and then wrongly conclude they "found" the
problem.

...and this is the kind of BS that gets people like me riled up.
Where do these "safety factors" come from? I'm not arguing with the 4
W/kg part of the standard. What I really object to is the notion that
for *occupational* limits that we aren't supposed to approach even one
tenth of that amount. Who are we protecting and what are we
protecting them from?

Answering my own question somewhat: This is the "committee" approach
to safety engineering. You gather together a group of blind men who
all examine different parts of the elephant and then they get together
to develop a policy to deal with this animal. This is why so many are
getting such a bad attitude about a standard which should almost be
sacrosanct.

The problem is that when such specialists get together, nobody really
tries to look at the big picture. Instead they try to protect us from
ourselves. The result is this bogus safety factor. After all, why
use ten dB and 13 dB safety factors? Are these factors related to
modeling accuracy? Are they related to measurement accuracy? Duty
cycle timing accuracy? I think none of the above. I think they
picked that number because we all have ten fingers.

I rest my case.

Yuri Blanarovich <k3bu@aol.com> wrote:

> What was N6NB doing? Wasn't he ARRL employee/whatever?

Once upon a time, Wayne was an ARRL Vice Director. At the time this all came up on the FCC plate, Wayne was a member of the ARRL Bioeffects Committee. The short of it is the Bioeffects Committee chose to file independent comments with the FCC, as the ARRL Bioeffects Committee. Overbeck was removed from the committee, and the remainder soon resigned in protest. ARRL has formed the ARRL RF Safety Committee to take the place of those who were no longer willing to serve.

> What did ARRL do to object to FCC "standard" that has no basis and no linkage
> to harmfull effects?

ARRL's comments to the FCC asked that the categorical exemption for Amateur Radio continue under the new rules. The FCC decided otherwise. After that, ARRL filed a number of petitions for partial reconsideration with the FCC, and worked closely with its OET staff to help both fine tune the rules to be a better match for the ARS and to help the OET prepare its documentation. The League then continued on to prepare the book, RF Exposure and You, to help hams meet the requirements.

I agree, exposure at the level of the standard has no demonstrated harmful effects. Would you propose that the standard be set a level for which there would be harmful effects? The bottom line, influenced significantly by the work of the ARRL, hams are permitted to do their own evaluations, there are no paperwork or filing requirements with the FCC, the power levels that trigger the need to do an evaluation are appropriately set, on most bands, at power levels greater than "barefoot" level, so many hams don't have to do an evaluation at all. The burdens on the amateur radio service are not onerous; with RFX and You in hand, I have been able to complete the evaluations for most stations in under a minute.

> Who is asking hams to comply with "standard" that has no base in any studies or known facts?

The FCC. ARRL is asking amateurs to follow FCC rules.

See http://www.arrl.org/tis/info/rfexpose.html for info and linkages to easy ways to evaluate your station.

The levels have been set higher at HF to account for such transparency, Yuri. At the levels of exposure in the standard, the absorbtion by humans is at the levels as I described.

> We have unfounded RF "standards" and you are already "explaining" and defending

The levels of the standards are "unfounded" because they have been set at a level demonstrated not to cause harm. Are you proposing that they be increased to a harmful level?

I have not seen commercial products but here are the two methods I have used. In each case, I used a nice dry piece of 1x4 painted all over with three coats of exterior paint.

1. Once upon a time, you could buy feed-through insulators. The ones I used consisted of two ceramic pyramids, the bases of which fit together. There was a long bolt that ran through the two ceramic parts from top of one to top of the other. Dirll two holes in the board spaced the same distance apart as the twin lead. The bolt goes through the hole and the two insulators sit one on each side of the board. Thyis requires cutting the twin lead -- one end ties to the antenna and to one end of the feed-thru bolt, then you need another piece of twin-led to go from the inside end of the feed-thru to the tuner.

2. My current method -- and the easiest -- is this. Drill two small holes in the board spaced apart same distance as the twin leads. Use a drill no bigger than the wires -- I use 1/8-inch bit. Then, draw a straight line the length of the board running through the center of both holes and, using a thin saw blade, cut the board in half, splitting the holes. Raise the window. Put the bottom half of the board in the window; lay the twin lead in the grooves, set the top half of the board on top and lower the window. Goes without saying to cut the board same width as the window opening. Go the friendly local hardware store and pick up some felt weatherstripping -- stuff it in

any cracks. Another trick is to use two boards -- one only about 6 inches long, split it as described above to bring in twin lead. The other board is the width of the window minus the width of the twin-lead board. Drill big holes in the second board to pass coax, stuffing felt weatherstripping around the coax.

> ...and this is the kind of BS that gets people like me riled up.

> Where do these "safety factors" come from?

Clearly, the standard should be set at a level that is below that demonstrated to cause unwanted effects. The general reasons given for the 10X safety factor is that the modeling and testing that was used to derive the 4 W/kg threshold are not perfect, the correlation between some of the methods used and human beings is not completely understood and, as I started this paragraph, the standard should be set at a level that is below that demonstrated to cause unwanted effects. The 10X level was the one for which concensus was reached by a committee of about 150 people.

The 50X factor for general public exposure is less clearly defined. There are those (among them the members of the now-defunct ARRL Bioeffects Committee) that believe that there are "non thermal" effects to RF safety below the levels demonstrated to cause harmful effects. The studies that support this belief are not well understood or generally accepted by most of the scientific community, but such studies and ongoing discussion about them continues. The 50X factor was included as the only way to get concensus to get the standard in place at all. The present SCC-28 members are very much considering that one level should be appropriate and that if the controlled level is safe, then it should allply to all.

> I'm not arguing with the 4 W/kg part of the standard. What I really object to is the notion that
> for *occupational* limits that we aren't supposed to approach even one tenth of that amount.
> Who are we protecting and what are we protecting them from?

I would very much argue against setting the standard to 4 W/kg -- this is the level that caused demonstrated unwanted effects. Clearly, the level needs to be set lower than that. There may even be some justification for

setting a level even lower than 400 mw/kg. This level is a thermal load equivalent to putting on a light sweater. No problem for most people most of the time, but would it be appropriate to do so if one was already at maximum thermal load, perhaps outdoors in the sun at 115 F? Under controlled conditions, the person being exposed has knowledge of the exposure and presumably the training to know that if it is hot, he or she should limit exposure below the 400 mw/kg level.

How about those who are not aware of RF exposure and/or who do not know what factors apply under what conditions? Most of the time, you could "put a sweater on" your neighbors safely, but what about that 110 degree day, with a neighbor who is ill, perhaps running a fever of 103 degrees, just as an example? Can you say unconditioanally that adding additional thermal load to a person under those circumstances is safe? I cannot.

I think I would have significant reservations about the uncontrolled exposure levels except for the fact that virtually all amateur stations meet them easily. Those that run 1500 watts and indoor antennas do not.

> The problem is that when such specialists get together, nobody really
> tries to look at the big picture.

Do you really believe that those who had spent literally years of their lives to develop the standards did not try to look at the big picture?

> I rest my case.

I wish I had all the answers so that I could rest my case, too. I am sure that those continuing to do research and continuing to put a lot of themselves into the development of the next versions of the standards wish they had all the answers, too.

If you really do have the expertise to reach such a conclusion, I am sure you would be welcome to participate on the commmittee.

Jerry, W7WPX wrote:
"Why is it then most (all) commercial HF sites use 120 radials?"

Broadcasters on the medium-waves use 120 radials because it is economical for them to seek perfection and avoid FCC problems. HF sites rarely use radials because nearly all use horizontal antennas. HF users aim at the sky, not the horizon.

Brown, Lewis, and Epstein tested the effects of numbers of radials at 3 MHz. This was about 70 years ago. They tried various lengths of radials and various heights of antennas. Ed Laport summarized their results in "Radio Antenna Engineering" on pages 119 and 120.

Ed concludes that 1/2-wavelength from the antenna base is far enough to extend radials. In fact, he says that 0.4 wavelength and 120 radials are points of diminishing returns.

From one of Laport`s graphs, here are data for a 1/4-wave vertical antenna at 3 MHz using different numbers of 0.412-wavelength radials. Field strengths in millivolts per meter were measured at one mile.

n mv
2 120
15 155
30 170

Source record: 173857

Morning All,

I am a newbie who has is looking to put up a decent antenna in the near future so I have been watching this thread with interest since I live in Nevada where ground conditions are poor so the issue of radials is real. Radials are a pain to lay out and getting 0.4 wavelengths in a 0.5 acre lot is non-trivial as well.

So now comes my question. Using the Laport data in Richard's message below it appears that the difference between 15 radials and 113 radials is only 1.5 dB. With square law radiation (1/R**2) of the RF this translates to a 0.75 dB or 18% difference in range for a given signal strength. Looks like for those of us that are constrained the difference in performance is not huge. Comparing 30 radials to 113 radials with the data below indicates a difference in 1/R**2 of only 9%. Am I missing somenthing here?

Of course all this this is based apparently on a single sample of data in an unknown environment, still it is interesting.

Tom, W8JI wrote:
"The resistance we might "measure" at the feedpoint of an antenna is
often a "modification" of the loss resistances and radiation resistance
of the system."

A single 1/4-wave vertical with 120 radials of sufficient length should
measure a resistance near 37 ohms and the loss resistance is negligible.

Tom also wrote:
"That "resistance", even if we sort out the part useful radiation is
from, NEVER includes all the loss resistances associated with an antenna
near earth, The resistance can be all over the place regardless of
loss."

My experience is that volatile measurements are signs of either a
defective antenna system or the bad instrumentation used to make the
measurements. Most measurements made with good instruments in a good
system are highly repeatable. Don`t throw away a perfectly good bridge
just yet.

Tom also wrote:
"A measurement at DC is (at best unreliable and more likely)
meaningless."

Depth of wave penetration is limited to about 1/2-wavelength in ordinary
soil, more in poor soil, less in more conductive soil. DC has a very
long wavelength, so it really goes deep. But, an oil-man may look, feel,
smell and even taste oil sand and give a good estimate of porosity and
more. DC conductivity of soil in a wooden box may give a good estimate
of r-f loss if you have core samples down to the wave`s depth of
penetration at the appppropriate places, that is around the antenna where
it counts. The soil in the box must be representative of that in the
site, including moisture and compaction.

BC stations need conductivity in surface soil along the entire
medium-wave signal path.
It`s most important near the station where the current is greatest.

Sky-wave users need only conductivity in the soil at the surface where
their waves hit the ground.

Best regards, Richard Harrison, KB5WZI

When I was a teenager I worked "dx" using a TA31jr rotatable dipole on a 25 foot
mast. I'd dare say a good beam on a modest tower would allow you work a lot of
DX; often the skill of the operator far outweighs the few dB advantage of a Big Gun
station.

Go for it, and enjoy.

Pete

Why use 120 radials in an AM commercial broadcasting installation?
Actually, I don't know.

That said, I can tell you what I _suspect_ happened:

1. An authoritative engineer published a study in the early licensing
days of an antenna that arbitrarily used 120 radials, and found the
antenna worked well in a broadcasting system.

2. Licensing authorities, trying to do a good job in a regulatory
environment, decreed that a broadcaster's antenna should perform as
well as the above "reference" system.

Result: Either you put down 120 radials, or spend REALLY BIG BUCKS
proving that your radial screen is as good as the "standard". For the
station owner, it is much cheaper to go by the book. He can put down
radials for only a few bucks per hour.

Repeating - I don't really know, but I would bet money the above
speculation is pretty close. I have seen similar stuff in other
industries. Standards get "grandfathered" this way.

Except that when you're dealing with a thermal energy source, and
you're dealing with a healthy occupational situation, why not state
the whole equation thermally and allow the engineers/technicians to
determine safety?

>The 50X factor for general public exposure is less clearly defined. There

But the non-thermal effects are not well demonstrated. In fact, even when the studies indicate a "non-thermal" effect exists, it's usually such a small fraction of the general public (for example, childhood lukemia) that there is serious questions whether the data really demonstrates anything or if it's just a statistical artifact.

Standards should be realistic and based on what is known in controlled, repeatable environments.

>exposure and presumably the training to know that if it is hot, he or she
>should limit exposure below the 400 mw/kg level.

It might be healthy to climb stairs in a pleasant office environment. It might be totally different to climb those same stairs when the air conditioning breaks down. Shall we make standards for climbing stairs?

Why not state these standards for room temperature and an adjustment factor to account for different environments? Clearly, there will be some variation due to background temperature and the physical condition of the people being exposed.

Further, I'm not arguing that there shouldn't be an occupational and non-occupational exposure level. What I am saying is that one number with an arbitrary "safety factor" is a dumb way to express this standard.

>I think I would have significant reservations about the uncontrolled
>exposure levels except for the fact that virtually all amateur stations meet
>them easily. Those that run 1500 watts and indoor antennas do not.

That it for now. However the camel's nose is already in the tent. We already have a bunch of folks who have convinced the committee that "non-thermal" effects, though still questionable after decades of research, should be a part of this specification. We don't even know whether such effects exist and it's already part of the standard!

I think that we should base our standards on what we know to be repeatable and predictable. I have yet to read about research which demonstrates "non-thermal" effects with repeatable, predictable

results. Is this the new "fuzzy engineering?"

>> The problem is that when such specialists get together, nobody really
>> tries to look at the big picture.
>
>Do you really believe that those who had spent literally years of their
>lives to develop the standards did not try to look at the big picture?

Oh, I believe they tried. I don't think they succeeded. Blind men
will know various aspects of the elephant very well. However, they
are incapable of understanding the whole elephant. That's what
academia is all about. I don't mean to say that people with
impressive degrees and backgrounds should not be respected. However,
their views are just one more opinion in a pile of practical issues.
In the end, if the standard is not authoritative AND realistic, it
will fail.

>> I rest my case.
>
>I wish I had all the answers so that I could rest my case, too. I am sure
>that those continuing to do research and continuing to put a lot of
>themselves into the development of the next versions of the standards wish
>they had all the answers, too.

My case is simply that this standard is a farce.

The ANSI committees should have done better. My point is that they
have already made a bad policy. The RF safety thing has thrown flat
embedded safety factors on the table. Politically it will be next to
impossible to repeal those arbitrary standards. We are stuck with a
blanket of "safety factor" on an already tight standard which takes
undemonstrated "non-thermal" effects in to account.

The job of safety factors should be those of the engineer and the
engineer alone. They know better than the standard writers what the
situation will look like. So I strongly disagree with "safety
factors" fudged in to the standard. Most engineers reading this
standard won't know what went in to it. Shall we add the expense of
fudging another safety factor on top of the safety factor we may not
already know about?

Where do these fudge factors end?

>If you really do have the expertise to reach such a conclusion, I am sure
>you would be welcome to participate on the commmittee.

To be member 151 of an already bloated committee? Don't you realize
that's exactly what's wrong?

The feed through insulators are a good idea if you can find them. Try older farm supply places. Old electric fencers had to be kept indoors out of wx and the feed thru insulators for this work good.

2 bolts spaced same distance apart thru a board works well. Use brass if possible with wingnuts out side, so you can disconnect before bad storm and hook to ground, unless you have also rigged up a spark arrestor here.

I like the idea of just sandwiching the window line between 2 boards, but you don't have to. Just use one board and saw 2 slits to center of board and put the line over the slits. Trim the plastic on the line or the board to make it work and put a bit of silicone caulk or shoogoo stuff to seal. You can get the insulation tape used for pick up caps to stick on the board to seal out the wx.

What would happen if you just terminated 450 ladder line into a PL-259, used a double SO-239 bulkhead connector, then just started the 450 ladder line with another PL-259 on the other side? Mayby a 1 or 2pf bump?

I like the W9INN remote balun box too and am using one at present.

35 feet is fine. Get yourself a medium duty rotator and a fine tri-
bander and go for it. By the way, see if you can fudge a bit. They
will likely inspect it, so, install the tower and have it inspected and
approved. Then, stick a 10 - 15 foot mast on the rotator, put the tri-
bander at the 35-foot level then stack a couple of VHF beams on the
mast -- you can get up a respectable Christmas tree of antennas with
that arrangement.

I put up a 40 foot Rohn 25G. Rohn (or someone) sells 10 and 15 foot
lengths of very heavy duty (and very heavy) hard-drawn tubing expressly
for masts. My rotor sits 3 feet inside the tower with a thrust bearing
on the tower, thus, I get 12 feet of mast sticking above the tower. My
line up is:
-- tri-bander at 40 feet
-- 6-meter five-element
-- 2-meter 13 element
-- 432 24-element at the top
-- mast mounted pre-amps for 2 and 432.

I'm in a deed restricted area - also a bit XYL restricted - so looking for ideas on an HF antenna. My current focus is the attic of the garage. Not much height but it is an open area I can use. I can access it easily from the shack with 50' or so of coax.

The problem with the house attic is the amount of intercom and alarm system wires roaming around. Those are just going to be RFI magnets. I already switched the 6m dipole to the garage because it kept getting into the intercom.

Basically the garage is 20' square with a joist to peak height of about 8'. It slopes in from all sides up to the peak. I can put an auto-tuner out there since there is power. Biggest question I have there is keeping RF out of the tuner. If needed I could put a ground rod next to the garage.

I'm not trying to work the world but would like local and some national/international capability.

Any suggestions?

Be aware that Radio Shack does not make coax, it buys it from
a manufacturer and has it "house-branded".
Some years ago, I needed some RG-58X to feed my 40 meter
beam, so I bought some at R/S.
The address label on the box said Belden.
That coax is still in use and works fine.

Rich, what happens to ground loss when the soil has a very
low conductivity, in other words it behaves almost as an
insulator ? Dry rock is one such material.

Is there not a soil conductivity at which ground loss is a
maximum ? If so, what is that conductivity ?

Reg.

I'll be using a Radio Shack HTX-100. I've been a ham for 3 years but I've been operating mainly FM VHF and UHF as well as APRS. I passed my 5 WPM last winter but never really operated below VHF. Since the 10 meter band is wide open at this time of the sun's cycle, I thought it might be a good time to try to find a used rig that is not too expensive so I could get more experience on HF.

We'll probably move within the next 6-8 months so I don't want to spend to much money on something that will have to come down soon. I had planned on putting my tower up last fall but I decided to wait until I find a new house.

At this time, I have mature maple trees all around the house so it could be used to attach a dipole or a long wire. Someone also mentioned a half-square antenna. As I said earlier, I am still opened to all options...

Stay safe !

Message-ID: <3A4A8326.D76E5F06@SPAMearthlink.net>
Source record: 173774
Cross-posted to: rec.radio.amateur.antenna,alt.ham-radio.vhf-uhf,triangle.radio

I have a couple of 5/8 & 1/4 wave mobile (NMO) mount antennas that I want to mount on a mast (along with a scanner antenna) outside my home. My question is how best to achieve a ground plane for these antennas.

There will be two antennas, one cut for 146mHz and another for 444mHz, each identical with exception of whip length. I found a plan in the ARRL Technician book that describes the construction of a ground plane antenna for 2m and 70cm, however it uses a PL239 connector and wire where I want to use an NMO mount and antenna. Will the radials be the same length for each antenna or is there a way to calculate their proper length based upon the frequency?

I know that I could just buy a dual-band antenna (like I did on my truck) and be through with this, but that doesn't seem like much fun to me.

----------SNIP----------

They make damn good dummy load's particularly toward the lower end of their rated range,
Resistors with rare exceptions do not belong in antenna's.

They are fairly quiet and can do an modest job if one does not expect to much from them.
As I remember the model's I run across in the military showed an efficiency of little over 50%
toward the high end of their range and down around 20% at the lower end.
Put 100 watts in get 20 watts out, yes that will really peg those meters, Actually they had a use at one time but technology long ago passed their purpose.
Open wire, A balun and automatic or manual tuner will beat them every time.

For casual use they might be acceptable for anything serious go elsewhere,
The SWR looks good, so does a dummy load.

> readout?

I'd guess that the capacitor Q at 1MHz is quite high, and for only 12pF with, say, 1 volt applied, the total current is only about 60 microamps. That means the current due to loss is in the nanoamp region. It's a very difficult measurement to make. (Note that calibrating with a short is _probably_ actually calibrating with a low-value, low-Q inductance...so what you told the meter was an in-phase current during calibration, was probably actually a slightly reactive current.)

Suggest you put the capacitor in a tank circuit and measure the bandwidth. The _tank_ Q is then (center frequency)/(bandwidth). Use that to compare with a capacitor with known Q. One problem you will have is that the tank circuit is completed with stray capacitance as well as capacitance from the capacitor you are testing, and it can be difficult to separate out the effects. Another problem is that usually the Q is mostly determined by losses in the inductor, not in the capacitor, for good capacitors, and as a result, it's hard to determine accurately just what portion of the loss is in capacitor. For example, if you have a capacitor Q ten times the inductor Q, then only about 9 percent of the loss will be due to the capacitor. A 1% error in bandwidth measurement translates to more than 10% error in capacitor Q if you assign a constant loss to the coil.

Another way that occurs to me is to put a fairly high, known RF current through the capacitor and measure the capacitor's temperature rise. You'll have to calibrate using something like a resistor the same size as the capacitor under test, I suppose. Even this method doesn't completely get around problems of loss in other parts of the circuit, because there will be sizeable loss in the conductors leading to the capacitor...and it's worse for small conductors that would otherwise reduce the heat conduction from the capacitor and make its heat easier to measure.

But...why? Do you expect the capacitor losses to be significant
compared with other circuit losses?

>Gary7SLL

Hi Gary,

Everyone seems more interested in the magic 120 radials than in your
question.

The mechanics here are simply the Z's found at the interface or
boundary. That is, the wave in the air travels through a Z of more
than 300 Ohms whereas when it encounters the earth (in any form) it is
subject to a mismatch because that earth Z is substantially less than
free space Z. It is the mismatch that controls the mechanics of
reflection and even if the ground is lossy. If it presents a
substantial Z differential to free space, then very little power will
be lost to ground (the mismatch reflects most of the power and very
little of the wave is actually absorbed in the loss of ground).

Thus the quick answer to your question above is - yes - ground
Resistance (Z) is significant to the process of reflection. the
significance of that ground resistance is found in the differential,
not in the absolute value. The greater the differential the better.
(I would add that it necessarily follows that earth Z should be as low
as possible - if you can control that factor. Contrariwise, a
exceedingly high earth Z would perform the same job just as capably,
but attaining a very high Z is for all practical purposes - far more
difficult, if not downright impossible.)

Now to the second part of your question (part B). Most neophytes
presume that the ground condition at the base of the antenna is
responsible for the low angle launch characteristic. It is not.
Ground conditions near the antenna (within the first wavelength) are
responsible for MATCH conditions far moreso than launch conditions.
It is the far field ground that matters more for launch conditions and

again this strictly a function of the Z differential. The higher the mismatch to free space, the greater the reflection (the cleaner the mirror). If you could extend those 120 radials out 10 wavelengths, then you may drastically boost that Z differential (by driving down the ground resistance). However, this is a very difficult requirement to be met (your 10M vertical would have to sit in the middle of a football stadium sized ground field - scale that to 160M to discover the sheer size demanded!).

One compelling proof of this is found in the excellent reports of mobile operations within short distances from a shoreline. Water is not a very good conductor, but its Z is sufficiently low to present a very high mismatch to free space borne waves and thus presents a very good reflection surface. The near field earth conditions dominate the match, and the far field earth conditions dominate the launch angle. In all practicality we can control near field earth conditions far better than far field earth conditions (except when we purposely choose a site based on these considerations such as locating near a ocean shoreline, lake, or marsh).

Thus to answer your question in the context of this thread, shorter radials may be effective for a MATCH condition, but have no effect in the launch condition. The same answer could be applied to lengthened radials (that is, until they are some 5 to 10 wavelengths long) too.

It doesn't work quite that simple.

When a signal is above noise even a small amount, it is easy to cpy.
When it is just above or at noise, just the smallest change sounds
like a VERY large difference.

To some people, it doesn't matter and a loss of even ten dB means
little. Everyone they work is strong and a good path so they can give
several dB.

Other people would almost kill for a couple dB.

In our applications "range" won't increase by 18 percent because the
range waddles around all the time with conditions. What will happen is
the reliability of the sation, especially for working DX, will
improve.

Also remember the soil losses we deal with are higher than those in
the AM BCB.

>Looks like
>for those of us that are constrained the difference in performance is not
>huge. Comparing 30 radials to 113 radials with the data below indicates a
>difference in 1/R**2 of only 9%. Am I missing somenthing here?

Not much. That's why, since I am a dyed-in-the-wool DXer on 160
meters, I use about 60 radials (one tower has 100 radials, but that is
my reference antenna that all others are compared to). I cringe when I
see people talking about 200 or 300 radials, especially when they are
short.

Keep in mind also that the more radials you use, the longer they must
be to be fully useful. Otherwise you may be wasting wire.

When the open-end spacing from radial tip-to-tip is .025 to .05 WL you
are at the flat part of the curve.

>Of course all this this is based apparently on a single sample of data in an
>unknown environment, still it is interesting.

It sure is. The thing that separates my station from some others are
all the "dB here and dB there" things I do. Do enough of the "dB here

and dB there" things, and pretty soon you are working things no one else can work.

That won't matter if you only ragchew, my friend W5TJ has no radials at all and is happy. But that's because he only works people who are 20 over nine. When it gets tough, the lack of five or more dB really shows.

Source record: 173781

Measurements made on straight lengths of 50 to 100 feet,
suspended in air, using instruments such as Autek and MFJ
analysers and home made bridges.

Zo found by terminating the line with say 150-ohm, 130-ohm,
120-ohm, 1/8-watt, metal film resistors until input
resistance remains flat versus frequency over a wide
frequency range. Checked by open and closed reactance
measurements on odd-numbered 1/8th wavelengths. Or by
drawing straight line through the mean value of plot of
ripple in input impedance versus frequency..

Attenuation calculated from open and closed impedance
measurements on odd-numbered 1/8th wavelengths. Checked by
magnitude of Z/f ripple when terminated with known resistor.

The values given are extracts from my measurement note books
made over many years. The measurements were not necessarily
made at the frequency at which the results have been stated.
It may be assumed attenuation increases in proportion to
squareroot of F.

They are accurate enough, plus or minus 15 percent, for any
amateur purposes. In any case results will differ from one
reel to another and one manufacturer to another because no
attempt is made to control HF characteristics.

The last sort of instrument I would use for HF loss
measurements on twin cable is a wattmeter unless made on 10
dB or longer lengths. If power measurements MUST be made
then the most accurate method is to determine the insertion
loss of the line by reducing the setting of a calibrated
attenuator in tandem with it.

The great drawback with calculating transmission
characteristics of twin lines from dimensions is the
uncertainty in the effective dielectric constant. It's a
mixture of air and plastic. Coax is fine.

"Silver solder" is a term traditionally applied to high-temperature hard solder alloys like you're describing. The ones I've worked with can be melted with a propane torch but not a soldering iron. But there are tin-lead solder alloys containing 2 or 3% silver to prevent leaching the metallization off of gold or silver-terminated surface mount parts. This has a melting point near that of plain tin-lead solder. Some people (mistakenly, in my opinion) call this "silver solder", confusing it with the high temperature alloys. They're very different things.

(There are also other low temperature alloys containing small amounts of silver, but mostly for special purposes and not often seen in electronics.)

Depending on how flexible your twin lead is, just bring it through the open window, then close the window on it. You probably won't notice any big difference. I've done it with no ill effects, but now I bring it through a wooden window frame with a narrow slot drilled through for the twinlead. Try it -- you might be pleasantly surprised.

Be aware that I once looked at the braid on my RS coax, and found it very sparsely woven; you could see the milky-white insulator of the center conductor right through it. Comparing it to Belden coax, you simply could not see through the braid -- no if's and's or but's.

If you buy coax from RS, just make sure you're getting their Belden stuff, and not something else...

Use four radials cut to one quarter of the wavelength of the frequency that you want to use - i.e. for two metres, you will want 50cm (or about 20 inch long) radials, and for 70 cms you will want radials that are about 18cm/7 inches long. The radials should be pointing down at an angle of 45 degrees from horizontal - this will (or at least should) give you the 50 ohms you should have at the antenna. For the scanner it will depend on the antenna, and what you listen on - the easiest option is to get a discone - benefit of this is you can also TX on it on both 2m & 70cm. Hope this info helps you out.

Cheers

Matt

The silver solder used in electonics, as opposed to plumbing and whatever else, usually runs from 2% to 6% silver and uses ordinary electronic soldering techniques and equipment.

OK, OF role call; how many of you worked on a Tek 'scope with the little roll of silver solder under the cover for replacing compenents on the little silver metalized ceramic strips?

Reg wrote:
"Is there not a soil conductivity at which ground loss is a maximum?"

Interesting question. As a transmission obstruction, it may be so. But as a constituent of ground-wave propagation or as a reflector of sky-waves, it would seem maximum loss would come from minimum conductivity.

Ground-wave propagation and sky-wave reflection require high conductivity for high efficiency. Insulation can only add loss if imperfect but doesn`t contribute much of anything to propagation of a ground-wave. Insulators are used as lenses to focus super-high frequencies, but don`t reflect sky-waves to any extent.

Nearly all ground-wave propagation curve sets begin with a theoretical inverse-distance or unattenuated field strength curve versus distance, and then add curves for sea water and soils of various conductivities. These curves indicate increasing losses as the resistance figures increase, or the reciprocal values for conductance decrease.

Surely copper is a better reflector of h-f signals than sea water or soil, and good soil is a better reflector than poor soil.

So, my guess is that more soil conductance is always better for radio propagation.

Best regards, Richard Harrison, KB5WZI

<Other stuff snipped>

Geez Roy, I thought we were talking about electronic stuff here.

Is this rec.plumbing.amateur ? :-)

Properly, the stuff used in electonics should be called "silver baring
solder", but since there weren't any plumbers around to correct us, we
called it "silver solder".

You are quite correct; the purpose is to prevent leaching from a substrate.

About the only place most people have ever seen it is the silver coated
ceramic component carriers used in OLD Tec 'scopes and some old military
gear.

It is still used in the manufacture of thick film devices and things of
that ilk. Those dip/sip resistor packs, for example, have their leads
crimped to a plated ceramic substrate and then "silver soldered" (sic).

Sometimes "gold solder" (sic) is used for parts where silver migration
is a problem, but not often because of the cost.

If you like, I can bore you for hours with tales of watching silver migrate
across substrates though a microscope and trying to figure out how to keep
it from happening without using gold while the Vandegraff generator across
the lab to simulate lightning effects on parts caused the secretaries hair
to stand straight up and brought threats of violence on my person....

Yes - I compared it on paper to several tribanders. None of them worked worth a hoot on 17 and 12 M. On the other bands, I compare it to tribanders everyday in pileups. They usually lose.

<snip>

Last sunspot cycle I was almost always on the road. I had a HTX-100, small power supply, and a wire dipole in my "extra" briefcase. Thumbtacked the dipole to the hotel walls and worked a lot of stuff.

If this is temporary, quit obsessing on the last db obtainable from your antenna and go hang a dipole as high as you can easily get it. If you have the space and coax, hang two at right angles and switch between the two for the best signal at the time.

You can pull the coax down and take it with you when you move; hams always need more coax for something.

When 10M is open, it doesn't take a lot to work a lot of stations...

5044. Re: QUESTION: Can shortened radials be effective?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-28 03:05:17 UTC
From: richardharrison@webtv.net
Message-ID: <7552-3A4AADED-110@storefull-111.iap.bryant.webtv.net>
Source record: 173794

The original question seems to have been:
Can shortened radials be effective?

Short can be offset by more numerous in most cases.

Ed Laport had something to say about short radials when discussing long-wave antennas. He observed that semiconducting soil attenuates the wave below its free-space value. Radials help reduce transmitting antenna losses. Vertical antennas must be used to launch ground-waves. At low frequencies these antennas are only a few degrees high. Radials for these antennas must also be too short in most cases.

To aleviate the short radial problem, Ed advises planting a ground rod as deeply as possible at the far end of each radial and connecting the radial to it. Ed also says that additional improvement may come from using above-ground radials to connect with the ground rods.

Best regards, Richard Harrison, KB5WZI

I have had the pleasure of using one of these little gems some
years back. A great RF instrument! The probe tip looked fragile
and I believe it could break off due to mishandling. I'm certainly
not expert on these, but my understanding is that the instrument
is essentially useless if you do not have a functional, factory-built
probe. I would guess that your prospects of building one yourself
successfully are rather slim. I hope I am wrong about this, but that
is, I believe, your situation. Sorry to rain on your parade. It will still
look nice on the bench, however. :o) 73, David K3KY
P.S. The factory probe plugged into the front panel to stow it and
to check calibration. As long as you kept it stowed when not in
use and avoided dropping it, they held up pretty well. I never
broke one but they always made me nervous! :o)

Which tribanders? The biggest attraction of the hexbeam is it's decent if not outstanding performance as a particularly small and light antenna. Most likely a Hex wouldn't fare too well against some 200 Lb. monster Force 12 with 37 foot elements for obvious reasons.

hey bill
i am glad you had good experiances dealing with customer service with mosley
i on the other hand have not in the past year or so i order a 9 ele 2 meter yagi
took them 8 weeks to get it to me then when i got it the quality of this antenna
was not a typical mosley antenna while waiting for the antenna after 4 weeks i
started calling and they gave me excuses after excuses why it hadnt went out yet
trying to get me to believe they didnt have any 1" diam tubing for the boom
then just a couple of months ago i needed to replace the hairpin matching wire on
my mosly diplowmat 6 meter vertical the woman taking the order couldnt find it on
the computer then when she claimed she did she quoted me $5 for the part and i
asked her if it was going to take 8 weeks to get this part(keep in mind all this
part is is an 1/8th in aluminum wire 3 foot long bent to look like a hairpin) she
said no it would go out in 5-7 days i said fine i will take it
then a week later i got a call from the office manager asking me what i really
wanted when i ordered cause it was unclear so i told her and she got it cleared up
said it will go out in a few days 2 weeks later i seen they had billed my credit
card for $23 so i called and they said the part was $10 and the other $13 was
shipping and handling keep in mind this is an aluminum rod only 3 foot long and
slightly larger around than a coat hanger i said okay just checking whats up and i
said has it been shipped she said not yet they are working on it this week well
again 8 weeks after i placed the order i had it in my hands
i know what yur thinking why didnt i just make the damn thing myself and if i knew
that it was so lightweight of aluminum rod i would have
i will never buy another antenna or order parts from them again i am only 39
years old but dont think i will live long enough to get the order in
i wont even get into the poor quality of the 2 meter yagi i bought and hated right
out of the box and never put RF thru it
good luck

hi rud
i would suggest getting a couple of big spools of 14 gauge wire and i would take the wire and follow the perimiter of the inside of the garage formomg a large loop then hook 450 ohm ladder line to it and run it to your tuner and that should be enough wire to get you out on most HF bands or you could wait til spring and put up a PVC flagpole with a multi band vertical hiding inside of it
good luck

5056. HALF SQUARE FEEDPOINT closer to 50 or 70 ohms?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-28 05:50:26 UTC
From: earlve3ab@igs.net
Message-ID: <3a4ad372.108529234@news.ott.igs.net>
Source record: 173790

I have ARRL ANTENNA COMPENDUMS 5 and 6 and there is a couple of
articles on half squares. Looks like feeding with 50 ohm coax (which i
would do if i were to build one)..might not result in a broadbanded
response...unless you perhaps use large dia conductors or something.
I want to try and avoid using a tuner. Im interested in 10 meters
first..anyone build a HALF SQUARE and feed at corner with coax.
IF SO ....do you have to use a tuner.73 Earl VE3AB.

Hi Reg,

Thanks for your suggestion. I'd probably do it your way except that I will be selling this house in the near future and I don't want to "damage" the window or frame, which are new units recently installed. I'll probably do the "holes drilled in a board" placed beneath the window for the time being.

Regards,

Rich Ardolino ? KB2CPE

From your earlier post, your tuner is designed for coax output. That is
no real problem - just use coax to run to the antenna - and use a current
balun at the antenna to suppress any common mode currents.

If you put up an inverted V cut for 10 meters, you should be able to run
it fine without even the antenna matcher. The SWR will not be under 2:1
for the whole 10 meter band, but it should be for the segment that is of
interest to you.

A dipole (inverted V) is probably the easiest to set up and match. Save
the long wire for later.

: length based upon the frequency?

A quick approximation is to use radials that are the same length as the
radiator.

You would be better off, on the base, if you used vertical that has some
gain over a 1/4 wave vertical. I would not use a mobile antenna, even
with a ground plane constructed for it.

Thanks for the information. We can assume then that measurements quoted
by others (but not done by the people posting them) showing much greater
loss are either in error or represent dramatically different dielectric.

LV,

For real-time propagation reports, take a look at http://hamdx.com and click on "Real time MUF map". It isn't quite as good as having something similar running on your own PC, but then, you don't have to input any data to this one.

Good luck,

Jeff

Source record: 173817

In general, any 20 awg or larger twin line, especially at low HF, will have a lower attenuation than RG-58 type coax, because (1) it has a higher Zo and (2) the wire diameter is greater than the coaxial inner conductor.

Every time Zo doubles, attenuation in dB halves.

Every time wire diameter doubles, attenuation in dB halves again.

It also winds very neatly around a choke balun.

And it's less expensive.

How information becomes degraded by many repetitions is illustrated by the 1st world war military message which when originally transmitted sounded like : "Send reinforcements - we are going to advance".

When the message finally arrived at battallion HQ, passed from one bloody trench to another through the shellfire, shrapnel and chlorine, it had changed to "Send three (shillings) and four pence - we are going to a dance".

Materials have permittivity as well as conductivity. A good insulator (low conductivity) will reflect radio waves with as little loss as a copper sheet. So is there some value of conductivity at which ground loss is a maximum ?

No doubt many people think they have such stuff right in their own back yard.

Roy, would Eznec provide an answer ?

The 4815A is a very sophisticated equipment (I have one and have repaired it, but not the probe, thank heavens). The RF signal voltage from an oscillator is applied to the D.U.T. The voltage across the DUT and the current through the DUT are *sampled* with 2 nanosecond pulses at a 5 kHz rate. The probe uses two balanced diode sampling mixers, one for voltage and one for current. The two sampled outputs are amplified by 5 kHz bandpass amplifiers in a closed-loop feedback circuit. Amplitude and phase are determined in this manner.

Finding a good probe may be possible from used test equipment sources, but they will be very expensive. Repairing the probe requires a special expertise in a special facility.

Consider making your own J-pole antenna, per:

http://www.thedragonmaster.com/j-pole.html

Minimal soldering skills, low parts cost!

Copper tubing versions:

http://www.qsl.net/wb8erj/440jpole.htm

http://www.cvarc.org/jpolescl.htm

They'll also work as scanner antennas.

I've never been able to make a mobile antenna work very well on
any mast. Once, a 2M mag mount worked fine attached to the steel housing
of an attic HVAC unit

What is the best way to tune a J-pole?
There seems to be three ways of messing up - the overall length of the thing, the placement of the cut (or length of the shorter element), and the feed point position. Can adjusting ANY of these things tune the antenna from way-wrong to spot-on? Or do all three have to be just right? Can one thing be wrong but compensated for by something else being wrong in the opposite direction?! Or would you tune each variable for the best results independently?

Plus, can you add extra length/sections at the top for more gain, and if so is that just a case of tuning a standard J-pole first and then adding the extra height while keeping an eye on the tuning? For 70cms you could make one (?) several wavelengths long and still fit it into a loft. Worth doing? Gain?

Any info appreciated, I keep meaning to experiment one day...

Reg wrote:
"Ed was an optimist".

True, Ed Laport was Chief Engineer of RCA International, and obviously believed most problems can be solved.

Ed reasoned that some r-f current plunges as low as 1/2-wavelength in ordinary soil. Driving ground rods at the far ends of radials provides an easy path between the tower and some of this deeper current and saves ground loss in distance between the ground rod and the tower.

Ed Laport built many radio stations from LF to VHF. He tested the ideas he wrote about.

Although more work, I strongly recommend the 10 meter beam, turned by a TV rotor. It will provide MUCH better performance than the other alternatives mentioned. Even at a modest height (say on a chimmney on your roof at 25 feet), you will get excellent performance. I did this about 20 years ago and was amazed at the performance.

Let me know if you have questions.

Reg wrote:
"A good insulator (low conductivity) will reflect radio waves with as little loss as a copper sheet."

The propagation mode must be considered. If the radio wave is guided by parallel wires or coax, interruption of the conductors with insulators can reflect the wave.

If the radio wave is traveling through a waveguide pipe, interrupting the waveguide to free space (an insulator) via a plastic waveguide window does not reflect the wave which flows right on out into free space.

In a similar way, radio waves have little reaction to insulators of various types in free space. Most insulating materials tend to slow the progress of the wave. This characteristic of plastics makes them suitable for microwave lens materials. We are familiar with plastic`s effect on propagation velocity when it is used in coax as a dielectric. But all of the plastic parabolic reflectors I`ve seen were coated with metal which performed the actual reflection.

Let's assume you do get the ladder line safely through the window. Now, once the ladder line is inside the house, if the operating position is 8 feet from the window, how do you route the ladder line to the tuner so that people in the house will not accidentally come in contact with it? Could you put it in 2" PVC until it gets to the back of the tuner?

> increase in loss with increasing frequency is too large.
> ---
> Reg, G4fgq
> ============================

Good evening Reg,

Hummm ... "method" you said ? ;-)

Well, it was seven years ago and I was not so competent as now, hi ...
(I do read your messages and those of some other contributors I appreciate only from two years ;-))

If I remember and with the few notes i have conserved :

I have get the Zc and Vf with a noise bridge, an adjustable R and my receiver.
I have used some 20 meters long piece of wire.
I have found about 100 Ohms for Zc and 0,66 for Vf.

I have realised two 1/2 transformers on toroids. (50/100 Ohms)

and for the attenuation :

TX / 6 dB power Pad / Step attenuator (HP) / Bird Wattmeter / T1: 50-100 / T2: 100-50 / Wattmeter for reference at the end of the line.

I set the power for a reference d viation at the end of the test line.

I insert the line between T1 and T2 and use the step attenuator (reducing the value ...) to come back to the standard deviation at the end (10 W ? don't remember ...)

The step att. give the attenuation and the Bird another very similar value of power increase.

Something empiric, is'nt it ?

But in fact, enough to say it's not a good choice for a performant antenna !

Another information : I have suspended the line some one meter above the ground, outside the shack ...

73,

Francis

Bill,

Am I like child plays big car? Get me out of the car.

The ckt is at 1.5 Giga Hertz. Two caps work with ustriplines at
inductive arms of HPF pi ckt respectively which is in front of a LNA.

The poor caps would cause the front-end stage to loss 2dB gain and get
1.5dB worst on NF. The fireman just told me the the cause is lower Q
from caps. I replace caps with diff. date code ones and they works.
Checking S11 at front end stage--- the difference is so slight. I
doubt the matching tolerance is that critical and try to find the way
to evaluate the caps. Any clues from the trap elements or ckt???

5086. missing ferrite rod- component tuner- ideas?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-28 16:12:22 UTC
From: salmonsm@missouri.edu
Message-ID: <92fop0$fn6$1@nnrp1.deja.com>
Source record: 173734

Hello,

I have a consumer audio-type am/fm component tuner. There is a post where the tuner's ferrite rod would have snapped into place, but it's gone. I am in the process of investigating a replacement from the manufacturer (Yamaha) but I'm not optimistic. Can anyone suggest a comparable (or better) replacement? I've just about talked myself into building a large loop (like the plans found at ftp://bbs.ks-huseby.no/html/loopant.zip.html) but then my room would be pretty crowded. Any more compact solutions out there? In addition to the post for the missing rod I also have one screw terminal for an AM antenna.

Plus, any tips for eliminating electrical/mechanical interference other than turning lights and applicances off? I have done so throughout the house and still can't rid tuner of a persistent pattern of noisy static across the whole band. Would it help to use the ground terminal, and should I use it the same way I would ground an external antenna (that is, fasten to a buried grounding rod)?

Thanks for any help!

Michael Salmons

Hi there,

visit www.cebik.com and go to technical section. Page down to the
vhf antenna section. Click on half square antenna 2m.

This is an inexpensive 2m antenna that has more gain over the jpole
and is made of #12 common house wire. 50 ohm match, coax fed
and held on a pvc frame. You can put this together fast and use it
along with the jpole.

Suggestion:

Use a simulation of your circuit to degrade a perfect 12 pF capacitor with a small series resistance. If the gain drops 2 dB and NF degrades 1.5 dB, you will know about the capacitor. Look also at S11. Look also at the simulated frequency response, which may not be correct. Your circuit and test equipment and simulator software are a good way to calculate the Q of the capacitor and to see the effect of poor Q.

==========

- - - - and a sure sign of carelessness in checking proof copies by editorial staff and authors. Editorial staff are almost guaranteed to overlook such things as incomplete squareroot signs. If that's the only one you've found you havn't looked very hard.

Even one glaring example like that is enough to cause loss of confidence in a whole bookfull of equations. It's the probability that more insidious errors exist, even less likely to be detected and corrected, which damage reputations.

Bob, I'm fairly certain someone like yourself would never take an equation from an ARRL publication at its face value without first of all checking it from first principles. Or waiting for a correction to appear in a later issue.

Like Terman's works, amateur radio publications are excellent collections of information and data. Very comprehensive reminders and value for money. But I havn't taken Terman as being the bringer of gospel truth for 52 years.

Everitt's work is another matter. In 52 years I have never found an error, not even one attributable to the printer.

However, although Terman's stuff may contain mathematical and similar errors, his theoretical explanations are undoubtably sound. Whereas amateur radio publications are littered with old wives' tales which are repeated, distorted and plagiarised ad-infinitum, from one issue to the next and from one newsgroup to another.

Some years back there was an article published in a British amateur radio magazine by a supposedly up-and-coming, high-flying, young author. Part of the article had been plagiarised from the USA "Radio Engineer's Reference Data". The irrefutable evidence of plagiarism was an error in the form of an equation identical to what I had detected some

years earlier in the original RERD publication. The amateur magazine author had not even bothered to check the accuracy of the stuff he was stealing. The RERD editors had not detected it. The magazine technical editors had not detected it. They probably hadn't looked. Two people wrote to the editors to point out the error. I was one. G5RV was the other.

But then, its only a hobby. ;o) ;o) ;o)

May I wish you a very profitable 2001.

An interesting comment, but you must define what you mean by "bandwidth is going to suffer". If you're referring to SWR bandwidth, you'll find that this is simply not true. The SWR bandwidth of the commercially available hex beam is excellent - less than 1.5:1 on each of the five bands covered by the five band model.

If you think of bandwidth in terms of forward gain and front/back ratio, then the "bandwidth" certainly is not the same as the SWR bandwidth, but I don't know that it is any narrower than that of the typical small tribander (or any of the available 5 band yagis). Larry Cebik covers this subject in great detail on his website and my practical experience with a real antenna tends to agree with his information. Here's the URL for the wire beam info: http://www.cebik.com/4.html.

Personally, I prefer the wide SWR bandwidth, provided that the f/b and gain are maximized somewhere near the frequencies I most often operate. That's true with the Traffie HexBeam.

Hummmm, Overall I agree except I'm not sure I would say the system in the near field has no effect at all. I notice reading about above ground counterpoises that they say the "almost perfect" above ground radial system has little effect on the vertical pattern due to the reason you give. IE: quite an effect as far as 10-20 wl out from the antenna due to the reflectivity of the ground at those distances. So I can agree with that, but I'm not sure I would say the radial system under the antenna has no effect at all. Or even just a little as they say. What makes me wonder is the plots I get when running verticals though eznec etc. Now, I'm not totally sure how that program jives with the real world in this case, but I do see an increase in gain at lower angles when using more radials. Say 60 compared to 2. Being as the far field ground is not going to change by adding radials under the antenna, I can't really see how there would be no effect from improving the radial system. Maybe not huge, but I think there is a bit of an advantage to the guy with more radials at low angles. The 1 dbi point at the horizon drops a few degrees when adding the radials. From about 15 degress with 2 radials, to under 10 degrees with 60. "Maybe 7-8 degrees". Am I missing something here? I'm not sure how that could qualify as no effect. The far field hasn't changed in these examples. MK

The value of the SWR is a big discriminator. If one has, or expects, high SWR due to using a single antenna on multiple bands, then go for the open wire line. SWRs of 50:1 or so don't produce as much loss as coax with an SWR of 3:1.

Hi Mark,

You are right, absolute answers usually expose exceptions.

Some months ago we had a very good example of how ground can be
suckered into playing for us vis-a-vis the fractal flyer (aka k2) or
my far more simple Lazy H.

Both use the ground as an element to find gain at low launch angles.
Thus we have an example of how ground immediately below an antenna can
affect launch angle. However, such opportunity comes at a great cost
- those designs are incredibly deaf overall with this one low angled
sweet spot of sensitivity. These "special" antennas are suitable only
to those with "challenged" circumstances. Another cost is that these
designs that optimize with ground are extremely sensitive to location

where a simple variation in height of only inches can drive the SWR through the roof.

Thus a more complex answer would have been yes - and no. Not a very useful answer to include not very useful examples. Your modeling presumes at least 60 radials (were they short as the subject is interested in?), which again removes that solution from the useful list (at least to those who have no alternative).

In all practicality, the near ground can at best affect high launch angles, but not the lower ones without considerable investment or trade-off.

Mark Keith wrote:
"I can`t really see how there would be no effect from improving the radial system."

Longer may be better.

A look at Fig.2 on page 3-5 of the new ARRL antenna book shows the geometry of direct and reflected rays from a vertical antenna. The two rays are parallel in travel to the same ionospheric area.

Suppose the angle with the ground should be 30 degrees. By trigonometry, the reflection point to take off at 30 degrees will be away from the base of the tower about 1.7 times the altitude of its origin.

Say we have a 70-foot tower for 80 meter operation. We would want good conductivity out to about 120 feet from the tower for elevation angles down to 30 degrees. In this case, the radials are about 0.43 wavelength. This is no test so I didn`t check my arithmetic.

Best regards, Richard Harrison, KB5WZI

5105. Radiation angle of Magnetic Loop?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-28 19:25:13 UTC
From: Peter en Helma Kerklaan <helma.kerklaan@icu.nl>
Message-ID: <92g44o$9u3$1@beast.euro.net>
Source record: 173752

Dear OM,

I have recently build a 1,5 meter diameter magnetic loop for 80 meter (I live in a area where a larger antenna for this band is giving difficulties).

While testing the antenna I have measured the radiation angle with a light tube and have find out that the point of maximum radiation is exactly in top of the loop. This means that it is transmitting at 180 deg. this seems to me as not very efficient.

The loop is at this moment mounted at 1 meter above earth, however reading the literature about this kind of antenna's this should not be a problem (is 1 meter just to close to earth?)
I have build the loop with the Capacitor in top and the Faraday Loop Match 180 deg below the C.

My questions:
1) Is this measured radiation angle what I should expect?
2) How to improve the radiation angle for "DX"?

I would very much appreciate some advice in this matter.

73, and happy new year!!

> lunatics in thier midst.

A good number of mass killers are hams. But they don't usually kill
other hams. They kill people they perceive to persecute, libel, malign
them, make them pay back taxes, etc. I'd grow eyeballs in the back of my
head if I lived in the Boston area.

>
> So much for Dr. Cohen being paranoid and stopping public ham appearances and

Yep, you gotta watch out for e-mail. That stuff will kill you every
time. I have a contract with the CIA to make "assassination" java
applets. I've made one that opens with a big picture of Dirty Harry and
his 44 mag.
He says "make my day, punk", and you puter shoots you. The bigger the
display used, the bigger the hole in your upper torso. As far as public
appearances, that may be due to excess "roundness". He may have trouble
getting thru the doors. Loose lids? Dunno, I've seen a few loose women.
But I've never seen a single one that used prozac yet. Thats usually
reserved for paranoid people who are afraid to go outside I think. MK

Hi Peter,

Your measurement only relates to near, complex fields that bear little
relation to the eventual lobe characteristics for this antenna.

So close to ground will be lossy, but obviously you have little choice
in the matter. Tuning may be difficult and/or bandwidth may be
extremely small (unless the loss opens it out again).

DX angles are largely determined by the ground found 10 wavelengths
out. Not much you can do about that except live near a lake, marsh,
or seashore.

Hi OM,

I would re-evaluate the need for "special facilities" given that
technology has progressed since these were constructed. What I mean
by this is that the circuitry is undoubtedly simple, but the parts

"were" exotic at the time of manufacture.

What was exotic back then is typical today. I would guess that surface mount components would meet every technical challenge (if you can reasonably find replacement values for the semiconductors (probably matched - and probably your greatest challenge)).

Hi Richard,

I won't check your math, but I will point out that where the ray starts out should be adjusted to the "current max" of the radiator, not the convenient tip. This of course pushes out the length of radial and serves only the enhancement of the 30+ degree portion of the lobe and not the 10- degree portion wherein DX lies.

Hi Again,

Hmm, on reflection, the logic above would suggest just the opposite
insofar as "pushing" the distance out.

Still and all, lengthening the radials to capture lower launch angles
doesn't seem to be SOP for any application.

Well, the example I had asked for was of ARRL material that was "scare
monger" in its presentation.

The example you gave didn't include any examples of scare mongering.

Perhaps you equate scare mongering and ARRL's financial structure.

Now, on to the topic that thread drift has created:

> Of ARRL Publications addressing the issue of EMR exposure and safety in
books
> and magazines that cost money for hams to obtain?

The 230 page book sells for $15.00 -- not exactly ARRL's major cash cow.
The main reason the book was developed was to document the way that Amateur
Radio responded to the rules. It has met that goal handily, with both the
FCC and IEEE SCC-28 noting that the book is an excellent reference that is a
model of compliance documentation. Not bad for being in print a couple of
months after the rules went into effect. :-)

The most important information for hams about the topic is discussed in the
QST articles made available for download at:

http://www.arrl.org/tis/info/rfexpose.html

Giving away the store is not exactly a cash cow, either, Rick. :-)

> Help me, Lord!

No need to invoke the Lord on this one; he helps those that help themselves.
:-)

Source record: 173765

Let me add to Richard's response.

As he said, you're measuring the near field, and the shape of this field can be very different from the far-field radiation pattern. You'd need to repeat the test at a sizeable fraction of a wavelength distance to get an idea of the true radiation pattern. But you don't really need to, since it's well known. As it turns out, the far field radiation is also maximum straight up when your antenna is that close to the ground. In fact, the maximum is straight up for any antenna height up to a quarter wavelength (20 meters) above the ground. As you raise it higher yet, the direction of maximum radiation slowly lowers. You can see this plainly with any antenna simulation program, including the free EZNEC demo at http://eznec.com. Or, because the vertical pattern is essentially the same as for a dipole, you can look at the diagrams in books like the ARRL Antenna Book, which shows patterns for antennas at various heights. (The horizontal radiation pattern is similar to a dipole's also.)

Even though the shape of the pattern doesn't change much as you raise the antenna from 1 to 20 meters, you reduce the loss considerably, so the signal gets stronger. This can also be seen with the simulation programs. The higher you get the antenna, the stronger the signal will be. Just because it radiates most strongly straight up doesn't mean it doesn't radiate anything at all at lower angles. But most of your power will be going in directions that won't do you much good, so it won't be much of a DX antenna. You're already handicapped by the fact that such a small antenna will be very inefficient (although this can be improved a great deal by construction techniques such as using very large diameter conductors and avoiding moving contacts, and by keeping the antenna well away from other conductors or lossy materials). Any antenna one meter above the ground on 80 meters will radiate straight up, be lossy, and poor for DX. A small loop will be inefficient at any height. The combination will guarantee a weak signal. If this is the best you're able to do under the circumstances, then use it. You'll be able to communicate, but don't expect to work much DX. The larger and higher you can make your antenna, the better it'll do.

If you feed your loop at the bottom or the top, it'll be horizontally polarized. The conductivity of the surrounding ground will have very little effect on the signal strength except at very high elevation angles, so it won't help to be beside a lake. At lower angles, the ground conductivity is important only if the antenna is vertically polarized.

Source record: 173768

Richard Clark, KB7QHC wrote:
"---where the ray starts out should be adjusted to the "current max" of the radiator--.

Yes, Richard Clark is correct. The approximate 1/4-wave vertical has "cosine current distribution", with 0-degrees at the base producing the maximum multiplier, (1). At the tip, or 90-degrees, the multiplier is 0 which matches the cosine and the current at that point.

But I wanted to reflect the entire radiator in the radial field, and so I did as Mr. Clark suspected and used 1.7 times 70 feet to arrive at the length for the radials.

With very little penalty from reduced reflection, as the part not reflected carries little current, the radials will do a fair job in reflecting slightly lower elevation angles for longer hops. Then for yet longer distances requiring lower elevation angles, the ground is out there to do its thing without added help.

Best regards, Richard Harrison, KB5WZI

Richard Clark, KB7QHC wrote:
"Hmmm, on reflection, the logic above would suggest just the opposite insofar as "pushing" the distance out."

Nice touch (on reflection). Richard was right the first time. It may be confusing as the angle the ray makes with the tower and the angle the ray makes with the ground must add to 90 degrees as long as the tower remains vertical.

At the surface of the ground, the angle of incidence is equal to the angle of reflection, which is the take off angle for the ionosphere.

My take off angle of 30 degrees needs a ray that makes an angle of 60 degrees with the tower and this strikes the soil at an angle of 30 degrees. So, it must depart, on reflection, at the same 30-degree angle.

The greater the distance to be covered in one hop, the lower the angle that needs to be made with the ground at the launching. This means the tower is farther away from the reflection point than for shorter distance paths.

Best regards, Richard Harrison, KB5WZI

I think you might find a couple of different ones at Goldmine Elect. Go to:
http://sales.goldmine-elec.com/
and do a product search. They're very cheap.

The MFJ one is a lot of fun and works great. I loaded up my 132 ft dipole, a window screen, a swing arm lamp frame, and other weird things. Non worked too great but they did load up at a 50 ohm match. I really thought my R-5 would work better than it did.

I'm don't know what the "americal radio relay league" is, but the media could care less that he was/is a ham.

I just checked four different news outlets and none of the ones I looked at even mentioned it.

A couple mentioned his Navy service. Should the Department of the Navy begin "damage control"?

All of them emphasised loner, weapons, and "bomb making" equipment, things that are exciting to John Q. Public. Ham radio, I'm afraid, is not.

In what way was his crime related to ham radio? Bernie Goetz was also a ham; I don't recall ever seeing this mentioned in the news items about his infamous subway shooting.

Trying to "damage control" in advance any potential misrepresentation by the press would be the most effective way I could imagine to ensure such misrepresentation by the press.

Unless you are trying to load up some really odd ball thing I doubt that you really need a tuner for 2 meters. If the SWR is bad enough to need one and you are using coax, then you will have enough loss the efficency will not be very good for the antenna system.

Care to tell what you are planning on using that you need the tunver for ?

Whom at ARRL did you ask? The ARRL Lab staff are not directly involved in these sorts of media-public relations issues.

If you asked in a thread on rraa, you did not ask ARRL. It is not even likely that this ARRL employee would have read it.

To give you my view, it would not be a good idea to try to "damage control" this unless there is an actual difficulty. What he did is not related to ham radio. I will, however, leave the decisions about that to those I believe to be better qualified than I to address them.

Francis, your measurement of Zo = 100 ohms is probably
correct for a power cable. VF = 0.66 is also OK.

But your attenuation measurements do not look good. When
the frequency is 10 times higher your attenuation is also 10
times higher. This is what happens when measured loss is
due to reflections and mismatch at the cable's terminations.

Your matching transformers may have as much loss as the
cable you are trying to measure. The transformer impedance
ratio may also be different from you think it is.

Your figures would be be better if Decibels = constant *
Squareroot of Frequency. Which is what usually happens on
cables at HF.

If you still have some of the cable perhaps you could
measure or estimate wire diameter over the stranding. Also
estimate distance between the two wire centres. I would be
interested to know these two dimensions please, in 1/10
millimetres if possible.

==========
Roy, YOU may assume measurements quoted by others are in error - but not I - at least not until I have full descriptions of make-up and dimensions of cables for which electrical data have been provided.

Physical descriptions provided so far are much too vague. It would be rash to jump to conclusions.

Is it asking too much for you to believe that I have some coax cable which has a loss much less than 600-ohm open wire even with a 10:1 SWR.

Outer conductor is 1" diameter. Inner conductor is 1/4" diameter. Solid polyethylene insulated.

Regards, Reg.

Hi Fred,

Are you speculating about the strong correlation between contesters
and murderers presented below? If such were so, then yes, there would
be a severe lifestyle issue in living in Boston. As always,
correlation is not causation - but given the source of this blurb, the
suggestion proceeds from a noted "authority."

This is only a problem in proportion to the bone fides of that same
"authority." No doubt this thread will become an issue of a victim
complaining of being castigated over a topic originated by the victim
and linked by the victim to the victim.

What are they going to do? Say he was listed in the DB, but he really
doesn't exist. Just a figment of their imagination. Just because the
president does this doesn't mean the americal relay league should.
Besides who cares...I bet it's hardly brought up at all in the press. I
didn't know about it until about 4 min you mentioned it.

Most of us probably do. I've got two shotguns within arms reach. Home
invasions happen daily in this town.
Anyone who comes breaking into this house is going to have a bad day if
they don't make a quick reverse when I level on them. I'd prefer they
left without the extra ventilation. I have better things to do than
clean up a big mess on the floor. MK

Hi Jim,

This says nothing of the aggressive effort being made here by the
original poster to make a positive (negative) link to Ham radio. In
demanding that the ARRL make some effort, it necessarily presumes a
responsibility that was not previously speculated nor assigned to us.

I knew a ham personally that went off the deep end, and shot his wife,
and then had his "girlfriend" kill him, and she killed herself. And he
was totally normal before that. I knew a ham on 75m that got into a
radio war where all the guys gave him a good tweaking, and he went
bezerk and shot and killed his wife. I know a ham that shot himself on
the radio. Live and I guess in color if you had sstv. But I wouldn't
call him a murderer. Then you have the post office guy in OK. He was an
extra class. On and on...Many hams are devos. Ain't no doubt about it.

5174. Re: Radiation angle of Magnetic Loop?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-29 00:03:09 UTC
From: Cortland Richmond <ka5s@earthlink.net>
Message-ID: <3A4BD401.39B91B41@earthlink.net>
Source record: 173671

If you mount a small magnetic loop so that it stands vertically, it radiates equally well (or, equally poorly!) at all vertical angles, with nulls in the directions perpendicular to the loops plane; if you sight through the circle, you are sighting along the null direction. If you mount such a loop horizontally, it will radiate equally well in all azimuth directions, with nulls at 90 degrees and 180 degrees elevation.

A small loop is NOT very efficient. Neither is ANY small antenna.

But in this case, I think you will find you are not measuring what you believe you are measuring. The light tube is probably responding to the high electrical field across the tuning capacitance at the top. You need to be rather farther away to measure its radiating pattern.

Why not just use it for a while? Others have had good results with carefully built magnetic transmitting loops.

And a very good New Year to you!

Cortland

Heck, I knew nothing of it, until he brought it to our attention. I have CNN going almost 24 a day on a tv behind me, and haven't heard a peep about it. I think the vast majority could care less. Many code toads are unstable in the same ways. I wonder why we haven't heard about that angle yet? Actually, I think the ratio of whacko code toads would outrank the ratio of whacko hams per population of each. But there are plenty of each types. In this case, you had a code toad who was also a ham... Double trouble... Kinda like me..g I wonder if I'm going to wig out someday... MK

i need antenna suggestions for a 75 meter antenna. here is what i have.

66 foot by 66 foot corner lot. house more or less in the middle,garage
on the side of the house. no trees on lot . 40 foot tower on the
opposite side of house from the garage. i can't put up a loop(xyl).

any ideas?

It will work well on 10 through 17 meters thats about it . A better choice would be a ladder line fed dipole as long as practical if your space is limited ,since you already have a tuner. Gary ki8dj>>Will it work?

I'd put up a dipole hung from the tower and just fit it in any way you can. Try to avoid an angle below 90% between the two legs if you can. You could have the legs tied off to ground stakes or whatever if nothing else around. I assume you want regional coverage. If dx, you could shunt feed the tower. But then you need to think about the ground/radial system. I think I'd just string the dipole up for a start. MK

Depends on what you want to work. A "drooping" dipole supported from the tower would be good for local work, and perhaps you could load the tower for DX?

I dunno, but I've heard rumors that antenna a pain to tune and get going. But I've never tried it myself. Could have been cockpit error I guess. Dunno.. I hate to slam it without trying myself. I notice cushcraft makes a little beam also that is kinda interesting. I think it's called the "director" or something like that. But I have no real world reports to it's worth. MK

Before everyone gets too hot and bothered, check out the CNN stories on McDermott. Also, the Boston Globe articles on www.boston.com. They say he only moved to Haverhill recently, not in February as someone showed on here from the callbook URL. I also noticed, from qrz.com, that his e-mail is not the one that the media refers to.

Haverhill is a pretty small town, but I imagine it's possible to have two Michael McDermotts..with electronics backgrounds...so let's not crucify this guy until/if we know for sure.

I can relate to this: when I was 18 I lost my lunch (at the school lunchroom even) when I read that 'Nathan Cohen' had been arrested for embezzling several million dollars. Of course, he was in a different state, let alone different town.

You don't get it, do you?

Even if the media finds out he is a ham, THEY WON'T CARE, NO ONE WILL.

Nobody but hams and those in ham related industries (and some extent, CBers)
care about ham radio.

There is no damage to control. Do you understand yet?

Yes, I have a call; same one since 1963. If you and your clone Chip care
so much, learn to use a computer and you can find out what it is.

I think the repeated cry for "damage control" says a lot more about the
mental stability of the poster than the murder being a ham says about
the general stability of hams.

Get one of those 102" whips from radioshack, mount it to the top of the tower, this gives you about 50 feet. Run a wire down to the bottom of the tower, and resonate with a coil. The approx dimensions for the coil can be found through software such as Helical3 found at http://www.btinternet.com:81/~g4fgq.regp/page3.html#S301

Floyd Sense <sentek@sprintmail.com> wrote:
: An interesting comment, but you must define what you mean by "bandwidth is
: going to suffer". If you're referring to SWR bandwidth, you'll find that
: this is simply not true. The SWR bandwidth of the commercially available
: hex beam is excellent - less than 1.5:1 on each of the five bands covered by
: the five band model.

Reduced spacing between the elements reduces the input resistance. This
reduces the efficiency of the antenna, as well as the bandwidth.

But then, all beam designs are a compromise, as you cannot maximize all
the desired features at the same time.

I think you will find all this confirmed in any decent reference on
antenna design.

5208. Re: Wakefield killer

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-29 04:44:36 UTC
From: Pete Holden <peholden@home.com>
Message-ID: <UEU26.89621$x6.41330780@news2.rdc2.tx.home.com>
Source record: 173706

I have it on good authority that one of the news services is reporting that the killer is known to have consumed large amounts of Frosted Flakes. The parent company quickly issued a press release saying that never in their advertising was it intended that Tony the Tiger ever encouraged, or even suggested, that violence was an acceptable way to redress grievances.

Despite this, medical authorities in Massachusetts have linked sugar consumption by people with inordinate interest in carnivorous animals to antisocial behavior. In direct response to citizen pressure, state senator Daniel Cravens has introduced a bill to ban the sale of all sugar (sucrose) containing food items.

Others have called for the registration of all pictures of carnivores. Registrants would have to complete a background check following an eight hour course in the storage and handling of said pictures.

Furthermore, the governor has issued a press release reaffirming.....

Pete, KA�TZK

PS Okay. Let's get serious. The killings were tragic enough. Let's not add to the insanity. If we "respond" won't we just be planting some sort of twisted suspicion in some minds?

: opposite side of house from the garage. i can't put up a loop(xyl).

: any ideas?

Purchase the ARRL publications on wire antennas. If you really want to
research the possibilities, get one of the publications that covers
vertical antennas - as well.

Let me interject a little bit of sanity here....

The overall U.S. murder rate is 6.8 murders per 100,000 population. So, if hams were representative of the population, we would be seeing about 44 ham-committed murders a year (based on a ham population of 650,000).

My guess is that it is nowhere near that high.

Stop worrying, folks.

Pete, KATZK

: Now you tell ME that this is just a random correlation.

Not exactly. But it is, however, a random observation.

Find out how many convicted murderers there are in the US, and then
find out how many of them were hams at the time they were convicted.
Compare that to the number of hams in the US divided by the population
of the US. That would begin to tell you something.

The mere fact that someone is able to name a few of the data points
where two characteristics meet does not in any way imply that the
two characteristics are actually correlated in the population at
large. (See "anecdotal evidence.")

Statistics simply do not work that way. (Someone else will no
doubt argue that statistics do not work at all, but that is another
story, for another NG.)

Yes, but there is something suspicious when ALL the loss is dielectric loss at frequencies as least as low as 3 MHz. Given the cable's dimensions it would be possible to work backwards and calculate what the dielectric loss factor would have to be to be compatible with the attenuation measurements.

What's the loss factor, TanDelta, of PVC containing red and black coloring pigments ?

]This is also a good option but in your area remember the wind load wil be
nearly double due to ice on the beam. Also take a look at the rotors insides
I'd bet the gears are plastis and those tend to break under very cold
conditions.

>3rd scenario: Something like a Carolina windom or a dipole between 2 trees
>near the shack. It would probably require an antenna tuner (other then the
>MFj-16010 though).

See senerario one on the windom. I would also look at a verticle such as the
Solorcon A99 or Anttron's 305. The A99 can be had for around 40- 50.00 Can new
and is an excellent DX or local antenna even at low elevation. I have one(an
A99) in the front yard at 6 ft off the ground with a set of homemade radials on
it, and an Anttron 305 @ 47 ft on top of the tower and they hear equally well
on DX although the 99 isn't worth a hoot for local, but at 20 ft and no radials
it did a great job both local and DX.

I recall several comments about problems tuning the HF5B - check the old newsgroup entries via deja.com. Also, check the manufacturer's claims for gain and f/b for all five bands. Don't forget that the HX-5B hexbeam has 10 elements - driven element and reflector for each of the 5 bands. And - there is no tuning required. On 17 meters, the Butternut information says it performs as a rotary dipole - no gain, no f/b. The hexbeam exhibits its best front/back ratio on 17.

""So Ed (Hare)..What IS the League`s major cash-cow, now that you`ve implied that there may be one?"

Ed`s answer hasn`t appeared on my screen yet.

The League is incorporated in connecticut, and for tax purposes qualifies as an exempt (not for profit corporation) organization under U.S. law.

The League can`t legally distribute surplus cash as dividends to member/owners. It spends its revenes on operations.

I think the League should be required to give a full and detailed periodic financial report to its members. If so, Ed Hare could answer the "cash cow" question by reference to the latest financial report to the members.

I looked through a 1998 QST issue received when I was a member, and found no circulation numbers nor commercial ad rates.

Ed implied that an ARRL book price was low and thus no "cash cow". Maybe ARRL hopes to make up in volume what it loses in price.

I would speculate that ad sales in QST produce more income to ARRL than member dues or publication sales. Being tax exempt is unfair to other publishers. Tax payers are real contributors to QST`s advertising business. Tax payers push the wagon while ARRL HQ gets a free ride.

Best regards, Richard Harrison, KB5WZI

I prefer 'em hot and chubby, myself. (The women, not the radios.) Since the power situation here in California is forcing us to run our heaters qrp, a warm woman is becoming more and more a necessity. As for hams being killers, consider this: National Rifle Association members presumably have a lot of guns, but one rarely reads of a killer who is also a member of the National Rifle Association. Hams own radios, but it's not uncommon to hear of a ham bumping someone off. Does this mean we should invent a new slogan, "Guns don't kill people, radios kill people!"

The same things can be said for just about any exempt organization; Sierra
Club, Greenpeace, MADD, Catholic Church, etc.

Do you want to change the exempt rules in general or do you just have
an ax to grind with the ARRL?

BTW, anyone else hear about the enviro group (forget which one it was)
that was selling mouse pads and had to recall them because they were
contaminated with some Brazilian jungle fungus?

Do you really believe that saying that a particular book is not a cash cow means anything other than that the book is not a cash cow?

Although such "flagship" publications as the ARRL Handbook and ARRL Antenna Book are a significant revenue source, I don't think that either of them is priced such that I would call them cash cows. The last time I was at a major book store, I got sticker shock by looking at the prices of some of the equivalent books.

What lie? You mean the question of why you started this crap in the first
place?

The word "you" can be singular or plural; posters from fractenna@aol.com
started and keep adding to this crap. Where's the lie?

If you (singular) don't like the association of your (plural) postings,
get a separate account.

> Why don'y you do something constructive like CALL this guy KB1EVA?

A totally insane comment not worthy of reply.

> Listen carefully. You need to DROP me as your focus. The new year arrives soon
> and it's up to you to make sure its a good one.

> 73
> Chip N1IR

Read carefully...

You are truely mentally distubed if you think you are a "focus" for me,
much like someone else we've been discussing thought the personel
department of his company was "focusing" on him.

Since you've bestowed the power upon me to make sure the new year is a
good one, I hearby declare peace in the Middle East, the end of malaria
in third world countries, and unlimited electrical power to all nations.

>the long wire for later.

Agreed: The dipole tuned for 28.4 will go up in a flash, and will get him on the air where he can enjoy radio. It will also serve as a reference antenna for the 3 el yagi that he will need as the band condx declines. With a low power radio and a dipole, you can hear more than you can work. The Cushcraft 10-3 at 30-35 feet will seem like a miracle!!!

See you guys around 28.4

C'mon Jim,

Getting even? Look at the other postings to observe the severe
back-pedaling going on - getting behinder is more like it. ;->

Odd how we hear of calamities from this source and they always seem to
be workplace related and an issue of dysfunctional relationships.
Remember the claim that hackers destroyed their site? The server
technicians pointed out that this was a problem of insiders, not
faceless hacks. How about the "anonymous" e-mail to the U? Again
server technicians pointed out that the source was internal.

Ed Hare made a very nice response to the ARRL questions. From the rates ARRL quotes for QST ads, and from the ad space counted in an issue of QST, several hundred thousand dollars a month are received in ad revenues.

If member numbers are multiplied by dues and divided by 12, this income would exceed ad income for at least some of the months, if I calculated correctly using insufficient information.

ARRL probably does not credit QST with all dues receipts as the subscription to QST may be considered only part of ARRL`s service to its members.

Ed is well justified on the basis of quoted sales of the little book in saying that the book is "no cash cow". I hope sales improve.

Best regards, Richard Harrison, KB5WZI

I'll add one I haven't seen mentioned yet...A cb antenna, or a homebrew vertical or ground plane for that matter. I'd much prefer the beam, but a GP can be mounted on a simple mast. There are many flavors. The cushcraft AR-10 is a simple fairly cheap antenna that doesn't require radials for decent operation. "A radial set can be added to further improve". Or any of the popular cb antennas will work. There is one I think is called a mako 5/8 wave GP. It's real handy as it uses a single turn loop of the type used on many 1/2 waves. So you can use the antenna either way. With the radials as a 5/8, or you can ditch the radials and shorten to a 1/2 wl and it will work fine. That is what I'm using on 10m right now. I got the antenna free but without the radials. So I use it as a 1/2 wave. The dipole will work ok for much stuff, but I'd prefer a good vertical anyday on 10m. The local coverage will be much better, and the antennas are well suited for dx which almost all the 10m activity will be. Junk cb antennas a great source for 10m antennas. 25 ft will work fine. If you can get a 36 ft radio shack mast all the better. A cb antenna at 35 ft will do great on 10. I'd rather have the beam, but much more work involved. Money too. BTW, Mines only at 20 ft right now on two sections of 10 ft fence rail. Still does ok. MK

The "almost perfect" above ground systems using four or less radials
are certainly critical systems...since the radials couple into
everything (including the lossy dirt below them) quite well.

My idea of almost perfect is a system that always works, and isn't
fussy. It also is a system that puts the RF where I want it instead of
where luck or chance dictates.

Well, if anyone has a schematic & parts list for the 4815A probe I'd
like to take a stab at building one.
Even if a homebrew version doesn't have the accuracy of the original
it would still make a usefull device.
If I get a circuit to work I'll be sure to post the results.

I've probably missed something, but it sounds like someone asked about
moving the feedpoint.

If it is a 1,5 meter loop on 80 meters you can feed it anywhere you
like and the pattern and loss is the same, as long as the feedline
isn't part of the radiating system and the loop isn't jammed right
against something conductive.

That seems about right to me, although this is, if memory serves, broken down more accurately in the annual reports.

> If member numbers are multiplied by dues and divided by 12, this income
> would exceed ad income for at least some of the months, if I calculated
> correctly using insufficient information.

Again, about right, although one must remember that ad revenues are related to membership numbers. It is also a bit more complicated because some of the ad revenues go toward the costs of producing the magazine; some of the dues revenues go toward the cost of mailing the magazine, etc. As a dues-paying member (yup, I pony up every year, too), I take some consulation in the fact that some portion of what the ARRL does for me is paid for by advertisers. Much better than seeing my dues at the same level as my IEEE dues rates. :-)

> ARRL probably does not credit QST with all dues receipts as the
> subscription to QST may be considered only part of ARRL`s service to its
> members.

I am not 100% sure of what this means, but if I do understand the gist of it, I will add that the majority of ARRL's revenues come from membership dues, ad revenue, pub sales and the return on its investment portfolio. (An organization that takes on a number life members had BETTER have an investment portfolio or it all comes down like a house of cards.) A smaller amount comes from individual donations, some to specific named funds.

> Ed is well justified on the basis of quoted sales of the little book in
> saying that the book is "no cash cow". I hope sales improve.

Back full circle, the book was not created to be a revenue source. Much like the content of the RFI Book, ARRL believes that putting the most important part of that information on its public web pages is good for the Amateur Radio Service. The book was created and priced low to help hams comply with the FCC rules on RF and station evaluations. The revenues fro the book partially offset the costs ARRL incurred in working with the FCC for almost a year and in then documenting the needed material for almost any related circumstance. I say partially because the rest was funded by membership dues and ad revenues. :-)

By equivalent, I meant equivalent in size and technical depth. As I recall, there was a large Windows programming manual (aftermarket, not MS) that cost about $100.00.

If you want REAL sticker shock, take a look at some of the book prices at http://shop.ieee.org/store/. :-)

Do you still beat your wife? The question assumes a whole lot.

It is obvious Prof. Beaker isn't a professor of logic.

Since the story was a head line story on the Los Angeles Times,
the Orange County Register, and every little local paper around, it
would be hard to miss if you EVER read a newspaper or just glance at
a news stand in passing.

Oh, sorry, PIM is in the bay area; it was also big news in the Mercury
News and Contra Costa Times.

You might try reading a newspaper once in a while.

It was on every news segment of every radio station of all formats; rock,
oldies, talk, easy listening, etc.

You might try listening to the radio on the way to and from work once
in a while.

It was on every news broadcast of all the TV networks.

Since you don't seem to know much about what's happening in the world,
you might also be interested to know Bush is now officially President
Elect, Elian is back in Cuba and Elvis is still dead.

Without any disrespect, I don't believe the ARRl publications are in this category. They are worthwhile for what they are--and I own them, including the leather-bound latest ARRL Antenna book-- but I would place them in categories such as one finds with TAB, CQ, RSGB, and other publishers.

I don't feel they are a 'bargain' in comparison, but priced at the top end for what the market will bear, and priced to tradeoff volume versus price.

Try running a wire arounr the perimeter of the garage, as high as possible,
in essence, a horizontal quad. feed with 2 -75 ohm coax, shilds connectred
together at ends, to make a ballanced feed line. use an appropriate antenna
tuner. hould work on 40 and up for an average garage.
If it don't worl as well as you'ld like, quietly take it down and try
another. A folded ZL-special might fit.

>Aren't most hams wacko?

Most of the ones I know are wonderful people and not "wacko" at all. There are rare exceptions, of course.

>Proof is on r.r.a.p.

Proof of what? Perhaps a dozen people regularly post there. That's about .00176% of the US ham population. And no way is it a representative sample.

Of that dozen, there are only a few "wacko" people. One guy says he may be a 300,000 foot tall space alien and waves his IQ around at the slightest provocation. Another isn't a ham and keeps changing his AOL screen name for some reason. A third thinks it's a chat room and mostly posts "LOL" and other nonsense.

The rest just like to argue.

What class license does this Wakefield guy have? What organizations does he belong to?

I'm amazed that we have so FEW "wacko" hams. I figure that since 1970 there have been at least a million different US citizens with ham licenses, yet only a couple of them have turned out to be violent criminals. Compare that to a random sample of a million Americans.

Note also that Timothy McVeigh didn't use any guns.

The above is very true. Since you would have a non-50 ohm load on the line,
the line would "transform" the impedance. So the closer you can keep the
mismatch to the matching network, the less the transmission line will alter
the impedance.

I agree that the ARRL pubs are not in the same technical category as IEEE pubs.

Some of the ARRL pubs are, IMHO, on a par with TAB's books, which tend toward the lower tech presentations, as a rule. Some, like the ARRL Handbook and Antenna Book, are on a par with the RSGB books, which tend toward the higher tech end.

> I don't feel they are a 'bargain' in comparison, but priced at the top end for
> what the market will bear, and priced to tradeoff volume versus price.

I don't imagine that any major publisher would consider ARRL books to be "volume" in any sense of the word. Do you feel that the couple of hundred RFX books sold any month are trading volume for price? The RFI Book, another book that I reasonably closely monitor, also sells 100-200 per month.

The >1000 page ARRL Handbook sells for $32.00. Do you believe it would be possible to produce a book that sells in the tens of thousands per year at a significantly lower price?

I do think that the pricing on the books is set at whatever reasonable level is believed will maximize revenues minus cost. OTOH, the ARRL Board of Directors would never stand for pricing it believed to be predatory. :-)

I know this post might be off-topic but could find no other newsgroup that had "antenna" in its name. I'd be most appreciative if someone could point to a more suitable discussion or other source of information.

I've seen advertised a device that claims to allow you to use the electrical wiring of your house as a tv antenna. You plug this device into an outlet, and then use connections it provides as your tv antenna.

I'm trying to find out if this actually works but have not been able to find any reviews.

Pointers to sources of information would be appreciated.
Email please, to tgirwf@bigfoot.com

Thanks in advance,
and please excuse this "close-to-off-topic" post

Richard

I think I may have discovered an important correlation:
1)The latest QST on p.9 implies that hams who are cw ops are more satisfied hams.They get more satisfaction because they know the code.....I am a cw op...and I know I do.
2)This guy's was probably a NO-CODE Tech, hence didn't know the code, wasn't a cw op....was not satisfied with just being a NO CODE Tech....and hence...
3)Capped all those poor innocent people.
Maybe the FCC should start doing background checks before issuing NO-CODE Tech licenses.
Seasoned CW ops are satisfied, happy people and would never hurt anyone.

Those devices have been around for years. Most of them, if they contain
anything at all, contain a couple of capacitors.

The cheapest pair of rabbit ears sold by Radio Shack will work better
than one of these things.

> I'm trying to find out if this actually works but have not been able to
> find any reviews.

This device will receive some signals. However, house electrical wiring is
not a very good VHF antenna system for a couple of reasons:

First, it is very difficult to predict the direction that the house wiring
will best receive from. It is quite likely that the antenna pattern will
have all sorts of peaks and nulls, sort of as if you had a rotatable TV
antenna that was pointing in several directions at once. This may not pick
up much of the TV signal you want to pick up or may have multiple responses,
resulting in ghosts.

Also, an electrical power line can be a very noisy place. All sorts of
electronic devices on the line, from power-line equipment itself to every
motor or power supply plugged in near you may create noise that will
interfere with the signal you want to receive.

If you have no other antenna choice, that device may be useable, but I don't
think it will work as well as a good set of "rabbit ears" on top of your TV.

Hi Ed,

In all practicality, this is a vanity publication given that your
contributors are unpaid - correct me if this impression (that is all
it is at this point) is out of kilter. Of course there are probably a
number of other (trade) journals that qualify for my aspersion of
being vanity pub.s too. (yeah, I am painting with a very broad
brush.)

This, however says nothing of the greater good of providing a means
for those who wish to publish, and wish to publish to their peers. No
professional outlet (acadmic/business based) would serve this need.
Hence, as I see it, the job of publishing these tomes is found in the
editorial work of combining, assembling and proofing copy.

There is also the issue of the intended audience (once again this
relates to the notion of peerage - not to be confused with those
holding title or the initials KBE). Here, there are no other
"equivalent" works aside from those already identified (TABS and etc.)
which sometimes actually go beyond the imposed label of "professional"
coverage (this is a point of contention because many professionals use
these publications too - hence the field becomes somewhat hazy when
"professional" is tossed around like academic honorifics are here in
this group).

Some here would hold the ARRL to higher standards (read: inappropriate
expectations to meet professional/academic standards) and yet decry
every posting of a passage from such an example of a superlative text
as being name-dropping (standard trolling). The higher standard is
not in the factual accuracy, it is in the conveyance of idea in a form
suitable to the intended audience (there is no such thing as a single
source of knowledge). In other words, those critics are guilty of
effete snobbism. Frederick Terman's works were classics of writing
and being easily absorbed (at least one such snob insisted this was a
function of plagiarism - imagine footnotes are proof of stolen work,
where the refusal to reveal source material is perverted proof of an
original unzipped idea - yeah sure).

Now to return to this notion of vanity press and your question about the price of the book and its comparison to 1000 pages (rather inappropriately posed question which suggests that knowledge is bundled by the pound). Given a score of willing unpaid contributors and my own effort to shepherd these writers into a coherent book, then yes I could do it cheaper. However, I don't have the overhead costs of the ARRL (not an issue whatever that burden may be) and I could probably employ "predatory" practices to come in at less than $20 and still make a buck for my effort. However, that is not a very viable enterprise - a poor business choice even if it is profitable... once.

One fact of life that is lost on many AMATEURS is that most professional reference materials come from vendors in the form of application notes. What these notes lack in credentials they more than make up in actual REAL data with REAL WORKING implementations that actually conform to theory (but don't expect a doctoral thesis proving it). 10 pages of this material is worth 10,000 pages published by the IEEE. I think that Richard Harrison would agree that some titles published by TABS are far more oriented towards the professional than the academic or amateur. Fortunately, lacking that anemic academic perspective makes these same professional treatises accessible to the amateur.

Back to your question (again - suitable for quoting): Could I do it cheaper?

The short answer is Yes - but why - and not for long. The ARRL already does it well, has the appropriate focus, is already known to the target audience, and has committed contributors. These factors are the more compelling than the simple list price or tonnage. ;-)

Absolutely. This is a paperback! With very little advertising expense, defined distribution, and so forth, the ARRL must be making at least $8-10 per copy. It's likely that the Handbook keeps the ARRL afloat with a cash float of $500K-$800K/year. I am not suggesting this is money wasted; it probably is barely enough to keep the organization solvent.
.
>I do think that the pricing on the books is set at whatever reasonable level
>is believed will maximize revenues minus cost. OTOH, the ARRL Board of
>Directors would never stand for pricing it believed to be predatory. :-)

Not predatory, just realistic. The Handbook is certainly not priced to 'break even'. Nor should it be IMHO.

The tradeoff for most hams has become not whether they should buy the Handbook--but whether they should buy one each YEAR. In recent years the trend has been for hams to buy a new handbook every few years. Hence the volume sales has decreased , but offset by the repeat-delay sales, have plateaued at a comfortable level.

A good friend of mine is a publisher BTW:-)

The contributors to the Handbook are paid at a rate of $65.00 a page and up. "And up" is dependent on whether they can send material pretty much page-layout ready. When I wrote a few chapters for the Handbook on my own time, I didn't qualify for any more than the basic rate -- the editors here all think I am too wordy. :-)

The Handbook is NOT an engineering-level publication, although when I give "bent-cover" or last-year's copies to some of the non-ham engineers with whom I work, they are generally appreciative. It does contain a fair amount of practical information lacking in most engineering-level books. Its technical presentation is probably suitable for the more advanced amateur; it is not, IHMO, a book for a relatively beginning ham, although I do hope that most hams will grow to the point where they can derive some value from parts of the book. The Troubleshooting, Circuit Construction and RFI chapters are the most useful ones, of course. :-)

> Some here would hold the ARRL to higher standards (read: inappropriate

IMHO, the Handbooks of today have become a bit too high tech; IO would not want to see them made to a higher technical standard than they are if by that one meant a more complex technical content.

By "predatory" I meant charging $100,000 for each book for the three people who might actually pay it. :-) And the reason I cited the >1000 pages was to give people a rough idea of the relative production and printing costs, and to let them compare the $32 against similarly sized somewhat technical publications.

Before I came to work for ARRL HQ, I bought a new Handbook about every three or four years. This seems about typical. If I leave HQ and have to buy them again (desk and personal copies of ARRL pubs are a fringe benefit; we get to pony up dues just like everybody else, though), I would probably stick to the same pattern. Although there have been two major revisions to the Handbook over the 15 years I have been here, it is more likely that each year, several new projects will be added and some revisions made to each chapter. I know for 2001, the significant revision was a revised DSP chapter.

With the availability of lots of projects on the WWW (including the ARRL TIS web pages -- the Lab has made >500 QST articles available for download), the projects are not necessarily the major selling factor they were back when I used to buy a new Handbook when I liked the new projects it contained. :-)

Go to the amsat.org website and look under the files section. There is a program called fodtrack. Free tracking program for the sats. In it is a schematic for a rotor tracking device. It might give you an idea as how to do it using the parallel port of your computer.
The interface is very simple.

I count 1190 pages. With photos and/or charts or illustrations on
virtually every page. Plus full-color printing on the soft cover,
front and back. At $32 it's a bargain.

I'd challenge anyone to find a book with more pages, photos, charts
and illustrations -- at $32.

Jeeze... good-god-mighty... some people ??!!!!

5288. Question: Vertical noise lines on NOAA APT image

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-30 00:46:19 UTC
From: Pervert_Extraordinaire <valued_customer1@att.com>
Message-ID: <3A4D3060.7B02FA70@att.com>
Source record: 173536
Cross-posted to: rec.radio.amateur.antenna,rec.radio.scanner,alt.radio.scanner

[Followup set to rec.radio.amateur.antenna]

Hello,

I've been receiving weather sat images for several weeks.
I've progressed from an unmodified Radio Shack 2006 scanner
with a Discone antenna, to a Hamtronix R139 receiver with a
home-brew QFH antenna. My image quality has improved as I've
modified/upgraded the hardware. However, I'm at a loss how
to improve further.

My present setup:

Receiver:
-Hamtronix R139 Weather Sat Receiver
http://www.hamtronics.com/

Antenna:
-Home-brew QFH antenna, located at ground level
-50' interconnect, RG-213U coax, soldered PL259 and BNC
-antenna made with RG-58 coax per the following.
http://www.rig.org.uk/Members/Software/body_software.html

Demodulator:
-Dell 600Mhz, Turtle Beach Montego II A3D 320 sound card
-SatMon
http://www.satsignal.net/

I am getting vertical noise lines across the image. It appears
to be 60Hz related as there are 30 lines across one of the .250sec
NOAA horizontal scans. (120Hz) I've located the receiver ~10 feet away
from my PC, I've located the antenna as far away from the PC as possible,
I've tried disconnecting the power supplys for the speakers
and printers. I've turned off the monitor. I've moved the feed cables around
(with respect to my PC and PC power lines) but note little noise improvement.

I had the QFH located in the attic at one time. However it was connected
with RG-58 and had similar noise problems. I'm quite sure it I re-install
it (even with my improved RG-213U coax) I'd see the same noise.

I note the noise does decreases slightly as the bird overflys. This leads me
to believe the noise is entering on the antenna rather than my demodulated
(and screened) audio feed.

I do have a cell tower located 1/4 mile from me.

This appears to be my last major hurdle before obtaining quality images.

Any help would be greatly appreciated!!

This is a link to an example file.

Are you related to potty mouth Phil? Your language and grammar are
almost identical.

Or are you the Prof. Beaker that appears on the Muppets?

Congratulations, you are the first person from this newsgroup that I have
kill filed. Though tempted by others, you are the first to have totally
worthless postings; not even amusement value.

Since you probably don't know what "kill filed" means, I'll explain it to you.

I will NEVER see ANY post from you ever again.

So from now on you're screaming and swearing like a little child in an empty room.

You should hear the buzz on the downlink. I had a bad
power line insulator a while ago that even clobbered
NOAA-16's deafening roar. You may have something similar.

Remember all those ham fox hunts and similar activities?
Now it's time to put those skills to use to find where the
noise is coming from. I got some really weird looks but
found the offending power pole in about 10 minutes...

You might want to try using a small audio transformer to give you some isolation between the receiver audio output and the sound card input. Radio Shack has some that are suitable for this purpose. We had a similar problem at our club station, and this cleared it up.

Sorry, in a way, I ever started this flap. Nobody--including the ARRL's "for profit" pulication department--is getting rich off ham radio. It was a somewhat unfair of me to overplay the devil's advocate and suggest the League is parlaying a fat profit by scaring the beeejezuz out of hamdom by disseminating technical information about RF exposure. They aren't. The whole industry is struggling to survive right now, and any ham with a kid in engineering school knows the ARRL Handbook remains a "best buy".

Did you see the "wavy-ness" of the noise? I've been told
a 60Hz noise should be more fixed in period. Now I'm wondering
if it's something else?

> Remember all those ham fox hunts and similar activities?
> Now it's time to put those skills to use to find where the

Any suggestions on how to attack this. How does one
identify a bad insulator? Look for carbon tracks. ;-)

Thanks for the response!

In other words, inductively couple the receivers audio out to the
sound cards audio in? I suppose this would alleviate any ground
offset/loop problems between my receiver and my PC.

Am I correct?

A Few Weeks ago I had put out a message saying that Cushcraft had given me poor customer service. I had a R8 Vertical (6-40 Meters) and it had been working well and all of a sudden it just stopped working. I talked to them and they had me send the matching network back (The Black Box). A week after I returned it I got it back with a form letter saying it had been tested and it was fine. To say the lest I was unhappy with them.

Well I have to say that 3 days after I got the matching network back they called and left a message on our machine saying that they had sent me the wrong matching network and was sending a NEW one out that day. New Years Day I put it all back together and my Son and Neighbor helped me put it back up and its now WORKING GREAT AGAIN!

It took some time but CUSHCRAFT TOOK CARE OF ME!

I thought it only fair that I let everyone know after I had told everyone about the trouble I had.....

I still have the old matching box and if Cushcraft does not ask for the one one back I am going to take it apart and see what I can see. I think its a bad soder connection. It also had a much larger Cap, its the same value but its larger in size.... Hmmmmmm I realy want to tear it apart and figure it out.

73's Everyone and thanks for all the help from the group

Message-ID: <3A4D744F.695FDD69@eznec.com>
Source record: 173552

You're right as usual.

I was thinking of a larger loop, like a quad loop, where changing the feedpoint from the side to the top or bottom (assuming it's mounted vertically) changes the polarization. With a small vertical loop, changing the feedpoint doesn't noticeably change the polarization, like you said.

You can change the polarization of a small loop by rotating it from vertical to horizontal. But when it's very low, like the one the original poster described, you don't want to do this -- the signal is GREATLY attenuated when it's horizontal.

Roy Lewallen, W7EL

> cable you are trying to measure. The transformer impedance
> ratio may also be different from you think it is.
>

The transformers were tested with the noise bridge 1/30 MHz and back to
back with the Bird (50 Ohms).
The loss are not important : the two transformers are in the line of mesure
and the ref. power set before the insertion of the tested line ... Then, I
increase power, by decreasing the step attenuator, to restore the set
level.

> Your figures would be be better if Decibels = constant *

If i remember correctly this interference can be from another bird on the same freq. Back when i was messing with APT images NOAA shut off NOAA 12 for a while due to interference problems with NOAA 15. At that time i saw the same type of problem. I also had a problem with my pre-amp that gave me almost the same look, with that receiver you are using i doubt if you have a pre-amp...if you do try removing it for a pass or 2.

5314. RV installation trouble

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-30 11:34:57 UTC
From: Bill Clarke <billclarke@bigfoot.com>
Message-ID: <92khmj$t8k$1@newsfeed.logical.net>
Source record: 173565

Here is the problem:

Using an FT-100 in a 29' travel trailer equipped with a DuoTherm AC unit. The AC unit is controlled by a low voltage thermostat which also controls the furnace.

When keying the transmitter, the problem is the AC unit attempts to turn on - whether the thermostat is on or off has no control over the problem. The AC unit will partially run (at a low compressor RPM).

I have tried several "mobile type" antennas and still have the problem (screwdriver, Hustler, and Lakeview). It doesn't seem to make any difference - nor is the problem band sensitive. The transmitter will key the AC unit on 80, 40, and 20 in all modes (CAW, AM, & SB).

I found by using a pair of Lakeviews fed as a dipole the problem diminished about 80%. If I use a wire dipole, the problem goes away completely. The wire antenna can be in any proximity to the trailer - no problem.

The "mobile type" antennas were all mounted on the tongue and were well grounded. I tried various additional means of grounding such as radials - to no avail.

DuoTherm company said they never heard of such a problem, which is not a surprising answer. From a manufacturer I would expect such an answer. The dealer also had no suggestions.

Anyone else have this problem or have ideas about a possible fix?

Tom, for once I entirely agree with you. The position of the feedpoint on a small magloop, say less than a 1/5-wave in circumference, has no effect on the radiation pattern or on the polarisation of a received signal.

Also the ground induced loss is negligible when the bottom edge of the loop is higher than about 1.5 loop diameters above ground regardless of frequency.

The low-angle DX potential of a vertical magloop is quite good in the direction of the plane of the loop because the low-angle radiation in that plane is vertically polarised as from a short vertical.

Although theory predicts short antennas have low effeciency, the fact remains that many mobile antennas, which are very short for either 40 or 75 meters, appear to equal and often out perform large dipoles.
I have been active in a net which attracts both mobile and fixed stations on 40 and 75. I am very surprised by the performance of SOME mobiles at distances equalling the radius of the USA. This is true on 40 and to lesser extent on 75. In fact I have copied mobiles on 160 at about 500 miles with very good signals.
Many times these mobiles are as much as 6 or more db stronger than an equivalent fixed station.

I can only conclude, without absolute proof, small vertical antenna do radiate at low angles and the more power used allows these antennas to sound like high dipoles in some instances. The quality of the ground plane seems very significant. Usually best mobiles are 18 wheelers.

Rich,

The skin depth of radio waves in the ground is MUCH less
than 1/2-wavelength. At LF to VHF the characteristics of
ordinary sorts of soil at depths of more than a few feet has
little effect on the above-ground propagation of radio
waves, either for absorption or reflection.

Examples for -
Soil resistivity = 100 ohm.metres
Permittivity = 15.

Freq MHz	Skin Depth Feet
0.2	36
2	12
15	6
50	6
144	6

Skin depth in sea water at 2 MHz is less than 7 inches.

Sommerfeld sorted it out about 95 years ago. Terman had got
the hang of it around 1940.

It would appear Ed did the right things for the wrong
reasons. But that's how most of us operate anyway. Even
Tesla cooked the books.

You're not off topic Richard. Lots of folks here know about antennas.
I'd say don't buy it as its largely a scam. Its also DANGEROUS if it plugs to 120 vac.
The reason these things do-not work is TV and FM radio transmit at high frequencys. As you increase the antenna length you easily introduce impedances (a kind of resistance) which in most undesigned cases, makes the long wires useless.
Get a set of rabbit ears or a good outside antenna from some TV antenna supplier. Don't fall for the house wiring antenna scams.

Well It really does depend on what you hope to work on 75 DX? or Local?
With your setup if it's DX you after I'd put up a 1/2 Sloper system maybe
three 1/4 wires with remote switching fed at the top of the tower. If
Locally ragchew the go with an inverted vee.. it may be shortened if need be
by coils in each leg. this will narrow the band width though

The example I was thinking of was the one in the arrl ant book where they did a test on 10m, using an above ground counterpoise of 64 radials. Much better than 4 low radials. I think they proved it to be "near perfect" as they even had the test gear under the counterpoise with no problems at all. But very few hams put up a counterpoise that good on the low bands. I found 4 radials on a gp at 1/4 wl up to work very well. But that is the lowest I would go with only 4. And even at that height you could see an improvement by going to about 8-10. But I don't think it would be a huge difference. But I agree, stick 4 radials at an 1/16 wl or lower and you have quite a bit of loss. Going from it to a GP at 1/4 wl up with 4 radials is like night and day. The 1/4 wl high version pretty close to 50-60 radials on the ground in theory, and seemed to work the same in the real world. It'll eat the low antenna for lunch. I consider 4 radials near the ground a "not even close to perfect" ground...:{ MK

Source record: 173474

I need the matching box for a Cushcraft R-7000. The part number is MN-7000. Cushcraft's price for it is just shy of a whole new antenna so I was hoping someone might have one from a junked R-7000. If so, please let me know. Or, if anyone has a wiring diagram I might be able to repair it. It was damaged by a lightning strike.

Or, if someone wants a junk R-7000, let me know. It looks fine except for the box. I don't see any other damage at all. I'd expect to see something else damaged by the strike but I sure don't see anything obvious. I don't think it was a direct strike. It also wiped out some of my computer gear, telephones, answering machine, and $250 damage to my roof-top A/C unit. No damage to the house except we might have to re-upholster the chair I was sitting in... :-)

Brooke,

I am not sure if our instrument is -A or -B. Let me check it out when
I get in the office. However, I have measured the Q at 1MHz and full
span with that instrument. The wave was vibrating severely. I doubt
its viability.

All,

Thanks for those who has advised me relevant methods. Your advice does
get my brain some exercises. Summary:

-Working on simulation: rough but interesting in ckt view.
-Frequency resonance method seems to be the way out with high test
frequecy (xx00MHz). Finding possible way to implement it.
-Studying the limitation on those instruments.
-Digesting the tech note from www.Johansontechnology.com.

Finally, I would like to wish you and your family have a wonderful 2001.

Thread:

Oh! Uh... stupid me, I guess I just didn't get it!

Now I think I get it... we are being told here on this NG that we may communicate with N1IR on the NG at will, with the single exception of communications on the topic of fractals.

To communicate with N1IR on the subject of fractals we must use another conduit. Some other place on the Internet I guess, who cares?

Is this right?

If this is true, then I find the proferred information to be a non-sequitor, since, like most hams I have little or no interest in those impractical fractal thing-a-ma-jigs. What good are they????

However I was elated to read that "directive" at first, since I originally had the impression that N1IR and his band of merry harranguers (sp) were movin on! But now I see that ain't so...

Oh well, there's always next year I suppose.

Hi Bob,

Now that there is a commercial value applied to the spectrum (in the marketplace of auction), we Hams are supported by taxes too. Those frequencies that we have access to, if they were to be sold by Uncle Sam, then the US would derive an income. Denied that (by virtue of our "entitlement"), the US must seek some other source of revenue - taxes.

Taxes work for me, I also use the GPO. Elsewhere in this forum is a link to tax paid effort to create a propagation modeler VOACAP - I use that too. Taxes paid for the Mismatch Uncertainty calculator I got from NIST - I use that too.

There are also commercial correlatives to each of these - I use them too.

Make taxes your friend ;-)

5332. Re: Radiation angle of Magnetic Loop?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-30 18:44:38 UTC
From: Cortland Richmond <ka5s@earthlink.net>
Message-ID: <3A4E2C58.76A76EDF@earthlink.net>
Source record: 173479

The theoretical short antennas are not inefficient;it is when we try to BUILD a short antenna that we run into inefficiency. A theoretical antenna has lossless conductors and loading elements, where a real antenna has all kinds of losses.

I use the rule of thumb that the efficiency of a small antenna is directly related to the product of size, cost and weight, divided by "k" -- how difficult it is to erect. "k" for an easy to erect antenna is very high, and for a difficult to erect antenna, may approach 1. There should be a frustration factor in there too, to allow for the antennas that get thrown out because they are too expensive, hard to build, or to erect. (grin)

All this unscientific grumbling aside, it's well known that reducing losses improves the signal. The Bug-Catcher uses a low-loss coil. A large ground plane reduces IR ground losses. Raising the mounting point further from the Earth's surface on a vehicle also reduces current flowing in that lossy ground. Spacing coil turns to reduce turn-to-turn capacitance, moving a top hat away from the coil, mounting the anna in the clear, away from conductors; all these are incremental improvement s that show up in places like W6RCA's shoot-out results. And in our enjoyment of our hobby.

I have in my garage the makings of a small magnetic loop; about 20 feet of 2.5 inch copper tubing and a 15 kV vacuum capacitor. I don't expect this to equal a dipole on 40 meters, or even a vertical on 80. But it WILL let me get on the air without putting up masts in my tiny back yard and alerting the neighbors that they can blame all their electronic problems on ME. It could also let me null out muchof the locally generated QRN. I count those as positives. Maybe I should factor THAT into my small-antenna algorithm, eh?

Happy New Year!

Cortland

>Am I correct?

Hi OM,

This is the symptom I spoke of when we last discussed grounding and
the necessity to tie all grounds together.

An isolation transformer is a limited cure and sometimes the only
solution (there are designs where there must be separate grounds).
The limit is imposed by any other ground referenced connection that
bridges that core's isolation (like an rs232 connector to your
external modem). If you attempt to isolate your audio with a
transformer and a ground loop is reintroduced (or already existing) by
another connection, you haven't got a solution.

This last, the second (or third or fourth or...) existing path, is the
most pernicious. It simply goes to first principles - ground all
equipment to the same point. Do not cascade connections unless each
connection towards the central ground grows correspondingly larger -
and shorter (a contradiction at some level - but again this is not the
BEST solution).

Let me illustrate this last imperative of a weak solution. Your Amp
is at the end of this chain of ground connections. For whatever
reason it introduces 1 amp of 60Hz current into ground. The path to
ground is laced through your audio mixer board and then through 0.001
Ohms of wire to ultimate ground. You have your audio levels elevated
by 1 mV of 60Hz hum IF your audio mixer also connects to another
ground path by virtue of that audio input (almost necessary by
definition). Audio full output levels are frequently based at a level
of 100 mV or 1V. The difference between the two would be hum in the
background or hum over the signal. The solution is no hum at all by

breaking that 1 Amp path and sending it to ground separately from the mixer's ground path.

1 Amp and 0.001Ohms are not exotic characteristics. The 1 Amp is admittedly there through some mishap (we are amateurs remember) and in all likelihood would be overlooked if it did not introduce this Hum (it will probably evidence itself somewhere else too, but that is another topic). 0.001 Ohm is pretty aggressive, but not terribly difficult to achieve. There is every likelihood that your ground path encounters more resistance. However, you can tolerate higher resistances if you tie every piece of equipment to ground through its own path. Interconnects between gear will then offer paralleled paths to ground rather than series paths.

To add to the mix, there is another option - the ground plane. In this scenario, all gear ground goes directly to a extremely close sheet of metal (typically layered on the table top, or back of the bench) which in turn has its own beefy ground drop. This is a very attractive solution in that it also gives a level of protection to the operator too if it is part of the table top. It also is very useful for static control if you handle sensitive devices. It also is very low in Z which aids in noise control (non-power line related noise that is) and RF stability.

For maximum equipment protection the RF and Lightning grounds should be separate. A good protection for a tower is three ground rods a few inches from the tower legs. The connection should be at least #8 copper from each leg to the associated ground. The connection should not have sharp bends, but a smooth curve with 6 inch or so radius. An s-curve is OK. Lightning takes what it sees as the shortest path (least impedance). I have had success in keeping lightning out of the shack by putting a one turn loop in the coax and motor control line as it leaves the tower.

A tower close to the shack makes a very loud bang when it takes a stroke!

Bill,
It sounds like there are induced currents in the thermostat
wiring when you use an antenna that uses the trailer for part
of the antenna sysem. You might try torroids on the thermostat
wiring as suggested, and maybe a 0.01 cap for by-passing.

5350. Catching FMcable stations

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-31 01:40:57 UTC
From: blairt@direct.ca
Message-ID: <3a548a4f.1095793@news.direct.ca>
Source record: 173498

A bit OT, but I thought some experts probably hang here who can provide an answer.
I am trying to hook up a JVC minisystem which I gave my girlfriend for Christmas, in order that she can receive cable FM stations. The JVC has the clip connectors for an external antenna, one clip for ground, and the other for "75 ohms". I have tried both using a matching transformer on the end of the coax, but this isn't effective, I guess, because it is really to match twinlead (300 ohms) to the back of the set. The owner's manual says to strip the end of the coax and insert the center conductor into the 75 ohm clip, and the braid into the grounding clip. This isn't working either.
Do I need something like a "matching" transformer that neither matches nor transforms, i.e. 75 ohms coax straight thru to the back of the JVC? At the same location,formerly,there was a 15 year old Mitsubishi receiver with a female insert on the back which took a male connector on the end of the coax which worked and received all the cable stations.
Compounding the problem here might be the fact that the cable signal has been diluted by several splitters around the house, although the Mitsubishi worked fine under the same circumstances. I tried the JVC, at a different location(another house) using a matching transformer and it captured the stations OK,.I was wondering whether trying a RS signal booster (25 bucks) might work if I am faced with a weak cable signal situation.
Any suggestions? (and thanks for the bandwith).
Blair.

I've found that CW ops tend to be stuck up self centered people that feel
that no one else is worth a damn unless they cow tow to their beliefs that
you're not a ham unless you can use morse code. I passed a code test yes but
i choose not to use it and i dont think Morse is the measure of the man and
should not hamper the growth of our hobby. My opinion.

The weather receiver drives the demodulated audio output via a LM380
amp which is, of course, referenced to weather receiver ground. The
PC sound card receives the demodulated audio input via <insert hardware
here> which is, of course, referenced to PC ground. Since both the
weather receiver and PC are powered by A/C, both of their references
are tied together.... but through a questionable path no doubt. Looks like
the transformer would make things worse since it would remove the least
impedance path (the audio feed shield) between the two devices.

> BEST solution).

Pernicious: adj. Destructive or deadly.

<SNIP>

I'm WAS wondering if I have a ground offset between my receiver and PC.
In both my old 'case' (RS2006) and new 'case' (R139) I've had my receiver
powered
via a connection to the wall receptical directly.... and my PC powered
via a connection to my surge suppressor and then to the wall receptical. This
would certainly 'lift' my PC ground above my receiver ground proportional to the
current/impedance of the surge supressor. This differential would be
counteracted
by the shield of the audio feed..... which would conduct current and generate
60Hz
noise. Hmmmm. However, I also experienced this APT noise problem when using the
receiver-speaker to PC-microphone connection to formulate the audio feed.
This speaker/micprophone is the mother of all isolation techniques.

Did you get a chance to look at my APT images? I've been speculating this noise is 60Hz based given I see 30 events over a .250mS synch. This is 120Hz. Each half wave of 60Hz injecting it's own individual grief. However, I've seen 60Hz noise on other APT images and they are more periodic than mine. The noise on my images appears to be less periodic. This makes me question my speculation.

Thanks again.

5357. Re: QUESTION: Can shortened radials be effective?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-31 04:08:16 UTC
From: Ted Bruce W2ICV <>
Message-ID: <hpat4t4kbg70oetbifc4bdo5uv2teps53p@4ax.com>
Source record: 173505

Tom,

That's what I'm looking for. Always works, not fussy. When I went from only 3 quarter wavelength radials on the ground to 5, my 20m vertical went from a flat swr, lossy dummy load to a usable antenna with better matching and better signals. Then I added 6 short (8 to 10) foot radials, and *subjectively* I feel that signals in & out got better. Also, the swr got a little steeper. I'm only 5 feet away from the lot boundary, so symmetrical radial patterns aren't possible. The soil is typical 2-3 inches of "woods dirt" (I'm surrounded by oak trees), 1 foot of Georgia red clay, and several feet of hard pan below.

I like Maxwell, Ternan, et al as much as anybody, but I also think Edison's philosophy bears merit...experiment, experiment, and experiment. If I waited until the most perfectly engineered, elegant design were complete for my antenna, I'd never get around to laying wire on (or under) the ground until I was buried with it. Sooner or later, you have to go with something like my interpretation of Moxon's approach: just do it. Otherwise, you get into a sort of Zeno's paradox...an arrow can never reach the target, because there are an infinite number of halfway points that it must try to pass.

73,
Ted W2ICV

I'd also look at the shield coverage. I recently bought some coax at
the Atlanta RadioShack.com store. The RadioShack.com house brand
RG-58U had about 70% braid, while their Belden RG-58U had 95%. I
didn't compare the RG-8's, since I was looking for lightweight qrp
cable.

Mr. Hammers:

As I explained to you last time, we will contact you when the antenna is
ready.

You were made fully aware that since your public actions, the only way we
would work with you is if we had the antenna back for evaluation. It has
been our belief from the start that your problems were due to installation
errors.

By having the antenna back, we can verify and document that the antenna we
shipped you works. All our preliminary ground evaluations indicate that the
component parts are checking out; however, we won't be able to verify this
until all the tests are completed.

Prior to sending the antenna back, you were made fully aware that no time
table would be set. I explained to you that you would be bumped for other
pressing matters, which you had no problem with. We also discussed any
possible delays mother nature could add as well as any other unforeseen
delays, which you understood.

Since you have continued to make this issue a public matter, I suggest you
give me your attorney's contact information, and I will have our attorney
contact him.

Sincerely,

G.A. Wurdack, Jr.
VP Operations

Mr. Hammers:

You should know R&D in antenna designs can take several weeks or several
months to complete a design from start to finish. I told you before you
sent your antenna back, that our product development schedule came first. I
am not going to rehash the delays, but you know very well that some things
cannot be rushed nor avoided.

We are very close to having your antenna's evaluation completed. I cannot
commit to a completion date as I am not involved in the evaluation, it is
out of my hands, but I am told it will be very soon.

The choice is yours. You can wait until we are finished and get your
antenna back, or you can proceed with your suit. As I am sure your attorney
has informed you, that process could drag this situation out for the next
couple of years and you would still be without the antenna.

We know the antenna design works. We have been in business for over 50
years and all our designs work and our reputation backs that up. You paid
for antenna that works and we are making sure that is what we sent you, and
if there is something wrong with yours, we will repair or replace whatever
may be defective.

Upon legal advice, this will be our last contact with you other than when
our evaluation has been completed. Any more e-mail demanding any kind of a
reponse will not be answered.

Sincerely,

G.A. Wurdack, Jr.
VP Operations

St. Louis, MO 63105

MY REPLY TO MOSLEY WAS AS BELOW

Let me see if I understand your position correctly.

Do you refuse to refund the money I paid for the Pro-96 ?
Do you refuse to agree to a partial refund for the Pro-96 ?
Do you refuse to return the Pro-96 without conditions ?

FINAL ANALYSIS FOLLOWS,
(Sent to me by a ham who wishes to remain anonymous.)

The only amusing thing about this is Mosley's attorney misspelling their
name in every instance! This really gives a lot of credibility to the "offer". Looks to me as if they have the same quality control at the plant
as they have at the attorneys office.

Once again Mosley or "Mosely" as your attorney refers to you--good job!!!!!

This "offer" to settle is not an offer at all. It is a release of liability
request to benefit Mosley, disguised as an offer.

Mosley is deeply worried about their public image and this disaster they
have created.
This vague "offer" is a veiled attempt at a public relations trick to fool
the general public and get Mosley into a position to claim to win the "good
guy/white hat award"!

Be cautious of the SPIN. They want to publicly say that they "offered" to
send the antenna back, BUT, Mr. Hammers is the one who refused to cooperate.
They will announce to the public that Mr. Hammers is the unreasonable bad
guy when telling their side to their customer base. They will conveniently

forget to mention the one sided unreasonable demands by their attorney. They
will not mention their current possession of (your paid in full antenna) AND
(your money)--both at the same time.

Their offer is shallow on the surface but if we break it down into parts,
one item at a time, one will realize that it is ALL entirely in their favor,
with nothing of any value or benefit for Mr. Hammers, except all the risk of
his investment and most importantly, the waiver of all of his rights. They
send him a box of parts and he agrees to release their liability. Fair?

THEY WILL SEND HIS ANTENNA BACK IF HE AGREES TO ACCEPT THE FOLLOW TERMS and ASSUMPTIONS

1. "The antenna is working properly" Do we take their word for it? By what
standard? A dummy load has good swr and the lightbulb of N6BT transmits.
Will this antenna perform as
well as the other Mosleys? Considering Mr. Hammers recent experience and a
check of the Champion Radio Tribander test, that would not be something to
brag about.

2. Why should Mr. Hammers pay even more money for his own travel to St Louis
plus
>accommodations to "view" performance in an unknown and completely unscientific environment?

3. New Warranty? Is it as good as the last warranty? The
warranty is only as good as the company backing it. In this circumstance I
see no value here.

4. If the antenna instructions are clear and complete they should not have
to imply fault to Mr. Hammers for a future action.

5. "Attempting" to put on colors? Do they have no confidence that they are
able to actually accomplish that minimum technical achievement?

6. "Assistance" Is the NEW Mosley assistance policy better than the OLD
Mosley assistance policy? No value here.

7. "Rights" Giving up all of Mr. Hammers rights!! Agreeing to come to Mo. to
file suit if it is necessary? I think not.

Are they suggesting pre determined liquidated damages as a penalty for exercising free speech? Libel isn't "libel" if it is the truth! There is no
penalty for stating the truth or how, where or how many times it may be
stated.

Are they attempting to short circuit the legal remedy process by attempting
to deny the
consumer even his right to claim possible misrepresentation or fraud?

After digesting all of their offers I see nothing whatsoever to benefit Mr.
Hammers. Also, I see a lot of very subjective and unenforceable "offerings"
with no value other than to gain the liability release for Mosley.

I suspect public opinion and pressure have come to bear and they realize the
public relations disaster they have created. Mosley's name and reputation is
on the line, worldwide, and they want out with absolutely no blame or liability, AND, at Mr. Hammers expense.

The antenna may be no better than before and they may well know it. Under
the terms of their current offer, once he gets it up, only then may he discover the same problems he found last time. However, this time they have
demanded that he give up a majority of his rights to protections afforded by
the law, and even if he ops to file suit that he must agree to travel to
Missouri to litigate it at their convenience in their local courts. This
demand raises another point. Perhaps Mr. Hammers needs to investigate the
fraud statutes and interstate commerce.

THE BIG QUESTION: If they are so confident that the antenna performs as
advertised--why do they demand that he sign away "all rights and recourses"
BEFORE they even ship it or before he gets a fair chance to test it? Hummmmmmm? Never heard of Force 12, Cushcraft, M2 or anyone else demanding
such an agreement prior to shipping an antenna. I think Mosley knows something and they are trying to cover their behinds in advance.

Question: What is it called when Mosley's attorney makes an attempt to force
Mr. Hammers to perform an act, ie: to sign an agreement under duress, not in
his best interest to "get back what he already owns". This is a fine line
here but there are legal terms which may define such at attempt. I am
surprised at these tactics by their attorney of coming dangerously close to
the line, if not crossing it by intent.

I suspect that 30,000 hams in Dayton, many of whom will stop by the Mosley
booth to ask about this and many refusing to do business with them will cost
them tens of thousands more in revenue than they will ever save on Mr.
Hammers buy back.

Mosley's position here is the classic example of trying to win a very small
battle while losing the entire war. The Ham community is watching (with
checkbooks in hand).

My suggested counter offer is twofold: Either of these would greatly benefit
the public image and perception of the Mosely company.

First:
The best solution for all concerned would be a quick, simple and liability
free solution.

AGREEMENT
Upon receipt of a full refund from Mosley, Mr. Hammers shall cease any and
all comments or discussions of this matter. Further, Mr. Hammers will notify
all interested parties that the matter is settled to the satisfaction of
all. Mosley company will retain possession after the refund, will declare
ownership of the antenna and have the right to resell it at will. This would
be the best for Mosley's public image.

Second: This second choice will work although there are certain areas, the
very nature of which are less than objective, which lend themselves to
differing opinions, thus a frustrating and time consuming continuance of

this unfortunate situation.

AGREEMENT
Mosely will immediately furnish Mr. Hammers with a complete
set of updated instructions
for his inspection and allow sufficient time for his questions and
comments.

Immediately thereafter, subject to Mr. Hammers approval of such
instructions, by mutual agreement, Mosely will ship the antenna back
to Mr.
Hammers at Mosley's expense.

Upon receipt of the antenna, Mr. Hammers will notify all interested
parties
that the antenna has been received, that positive progress is being
made by
both parties and will refrain from any comments until it is in the air
and
tested by an independent antenna expert, agreeable to both parties,
known to
this industry and at Mr. Hammers'expense.

Mosley will have the right to appoint a representative of their
choosing to
be present at the
assembly, raising and testing of the antenna.

The opinions of the expert will be made public via the internet to all
interested parties. If either party challenges the test results, each
will
reserve the right to
a second and final evaluation by a second tester, agreeable to both
parties
and at the challengers expense. The performance criteria shall be the
figures originally published by the Mosley Company.

If the antenna performs as advertised, Mr. Hammers will then publish
his
acceptance, cancel any existing actions, sign a waiver of any future
actions
against Mosley, (excepting all provisions of the standard warranty),
and
refrain from any further public
comments concerning this circumstance.

If the antenna does not perform to its advertised specification,
Mosley will
agree to refund all of Mr. Hammers money and upon receipt of the
refund, the
antenna will be returned to Mosely at their expense. Mr. Hammers will
then

notify all interested parties that the matter is settled and refrain from
any further public comments.

All statements included herein are all personal observations and opinions
sent to Mr. Hammers privately in an effort to aid negotiations for the
benefit of both parties and is not a suggestion of any legal action or legal
advice.

My personal opinion is if The Mosley Company continues to follow these
practices of treating customers in this manner, they won't have to worry
about the performance of their products because they simply won't be around
long enough to support the warranties on any of their products. So sad that
misguided and over principled managers could destroy such a good company,
long standing with a previously fine reputation. A reputation gone for less
than the price of one antenna. Foolish

THE OFFERS MENTIONED ABOVE WERE MADE TO MOSLEY, MOSLEY REFUSED TO
REFUND ANY OF THE PURCHASE PRICE. THEY EVEN REFUSED TO ACCEPT THE
PRODUCT BACK AND CHARGE A RESTOCKING FEE. MOSLEY REFUSES TO DELIVER
THE ANTENNA, ANSWER MY EMAILS, OR ANSWER ANY OF MY QUESTIONS TO DATE.
IF MOSLEY REFUSES TO ANSWER MY QUESTIONS NOW, WHAT WILL THEY DO IF I
WERE TO HAVE ANY PROBLEMS WITH THE RETURNED PRODUCT ? MORE REFUSAL ?

PLEASE LOOK CAREFULLY AT ANY COMPANY BEFORE YOU BUY ANY PRODUCT.
I GOT SCREWED OUT OF OVER $5,000.00, PLEASE DON'T LET THIS HAPPEN
TO YOU. For details on this disaster please see this URL
http://users.bentonrea.com/~wa7aw/tower/page14.html

I would be most appreciative if you would FORWARD this email
(in its entirety) to all who might be considering the purchase
of any new amateur radio equipment.

One of my xmas presents is a new force 12 5BA antenna, I will post
my experiences with force 12 after it arrives, and should the Mosley
get here before the Force 12, anyone want to buy an Mosley
Pro-96-S antenna really cheap ???

happy new years 2001

Donald,

I have had one up for close to 6 years now and am quite pleased. I have only wires and verticals to compare to but the difference is stupendous. I can work over 90% of what I hear on SSB and that is with a FT990 and 100 watts. I read people bad mouthing Cushcraft but I have certainly feel I've gotten my money's worth. Never had a problem with the traps or any other parts. It is mounted on the roof on a Glen Martin tripod. The difference never ceases to amaze me.

Ah yes, the velocity factor. All of this is good and nice but I
suggest that the inquisitor buy an ARRL handbook. It doesn't matter
what year. These questions are answered in every one!

I don't have a book handy but I do remember that there are certain
things to keep in mind with a 5/8 wave antenna. You can't just hook up
a piece of metal (cut to length) to the center of your coax and expect
it to work. I think that all 5/8 waves need a loading coil to match a
coax. Someone else might expand on this point.

No apologies needed. Myself, I don't use a kill file at all. If I see a thread that doesn't interest me, I just quit reading it. I'm sure it's annoying to the vast majority , but much of it is quite comical to me. I know if the comedy channel gets slow, Heckle and Jeckle will be cooking up something soon. Placed in a Peyton Place atmosphere of course...With Perry Mason as guest star... :+ Happy New year! Watch out for HAL 9000. He's getting cranky. MK

Hello Al, I was given a lot of help by Ham's when I was getting started with SWL'ing. They helped me with antenna's, and with information concerning the gear I drug up, and stations I was hearing. I started in the mid 60's as a kid in high school. I have not done much lately with either SWL or Ham, as my job keeps me pretty busy. I agree that we should try to help each other, and perhaps generate a little more interest in both areas. When asked, I always make time to answer the questions I can, or direct the folks to someone, or someplace they can get them. I at one time asked some very ignorant sounding questions, but the guys helped me, and as I learned, I looked at others asking the same questions as interested, not ignorant...

Well Bill NASA spent a great deal of money MUS$ investigating solder, and soldering reliability.
As I was working for them back in the 60s and 70s I was sent on a weeks course to learn about soldering and how to solder. There was an examination and a few test pices to complete at the end of the course. That fact that I passed with a good mark, and my memory though not perfect is not so bad that I would forget the few useful bits of information that I picked up.

Still we are probably discussing an obsolete technology if lead is to be eliminated from electronic equipment.
Of course the fact that in the olden days, (50s) one was taught (not NASA) to produce a third hand by holding the resin core solder in the mouth is ample evidence that everything that we are taught is not always true, and that one man's meet is another's poison.
And please don't acuse me of having a mental condition prematurly brought on by lead poisoning. ;)

Tectronix used to supply silver solder on little bobbins that formed a part
of the osciloscope in order to solder components onto the ceramic tag boards
that they used in their equipment.
Silver solder can be soldered with a number 9 curie point tip.

Of course some of us have been around long enough to have done it;
not just read about it.

Me sir Me,
How many of you repaired and calibrated them to a seconadry traceable
standard?
The handbooks that came with them were super, why more companies don't
introduce a little humour into ther tech data I do not know. A full day at
the bench can be tiring enough, the light relief from the humourous drawings
was a welcome.

BTW I agree about the slack naming of the silver bearing solder.
I have used the powdered silver for putting flanges on Q Band Silver wave guide and certainly that would only melt with a torch.

Source record: 173424

Reg wrote:
"The skin depth of radio waves is much less than 1/2-wavelength."

Ed Laport had smething to say about short radials when discussing long-wave antennas. At low frequencies, antennas and radials tend to be too short. What to do? Exhume the radials and drive long ground radials at their extremes.

Reg gave r-f penetration (skin depths) for waves of various frequencies in soil of 100-ohms per square meter resistivity, and permitivity of 15. For 200 KHz, it is about 36 feet. For 2 MHz, it is about 12 feet. At higher frequencies the soil`s capacitance tends to bypass the soil`s resistance, but soil capacitance is usually lossy,

I have no quarrel because I have not measured r-f penetration depths. I am aware that a wave spreads less when its progress is easy, but when obstructed, the wave tends to bypass obstructions. In poor soil, waves go deeper to get around resistance in the topsoil.

Ed Laport was likely writing for the worst case by saying waves could penetrate the soil down to 1/2-wavelength below the surface. I don`t remember his exact words, but I`ll bet he qualified the depth based on soil characteristics. I`d also bet he got it right. I am the probable culprit in not quoting his exact words in their entirety.

Best regards, Richard Harrison, KB5WZI

Get an antenna for the 440 mhz ham band, and snip off a half-inch or
so, or whatever it takes to resonate slightly higher at 477 mhz.

I didn't know there was a CB band on 477 mhz... something new?

I have done it too. However, I used *silver-bearing solder*, not silver solder
like I use to solder copper pipe with a MAPP torch.

I bought an antenna tuner for use with a 70' random wire antenna and my
Drake R8B. I did NOT find any advantage to using the tuner, in fact there
was a BIG DISADVANTGE in that you need to retune the tuner when switching
frequency bands.

Plug the long wire into the 500 Ohm "Antenna B" spring clip and enjoy a
great receiver.

Gary- my comments were in reference to the 'boiling' of Antimony, only. I have not found a reference to solders with this element , in what was a limited search. Antimony is used in several lead alloys that are commonly cast, because Sb, like water, but unlike most substances, expands when it solidifies on cooling. Thats why it is used in type metal, and in bullet casting- it gives a 'crisp' surface that is true to the die.

I have been using non-lead solders in some projects I am involved in, because they concern objects that are handled, and there are regulations that dictate 'lead-free'. I actually find the newer solders easy to work with, unlike some of the reports I have seen.

When I was active in Aerospace work, we had to have certified solderers. I was not one of them, but it was something we had to specify and certify. We sent many operators to Marshal Space Flight Center classes.

As to the 'Lead poisoning', I may have been more at risk than you- at one time- MANY years ago, I used white lead in some activities. We were very ignorant, and I now find that scary.

In one example I also show appx 12 inches, with the rod about 1 inch
from the element. "This type using the coax cap inside the rod". 3/8
inch tubing used. There should be a spot around there somewhere. How is
the beam mounted? If it's not mounted yet on a tower etc, point it
straight up when trying to tune. May cut down on coupling effects in the
area. MK

Only if you help me solve my noise problem. ;-)

I'm only doing APT (Automatic Picture Transmission). There are others.
The following is limited to APT.

A) Frequencies:
1) NOAA12 137.500
2) NOAA14 137.620
3) Meteor 137.300
4) Resurs 137.850
x) For Satellite Tracking, try SatScape at http://www.satscape.co.uk/

B) Decoder and receiving S/W
1) I used a Radio Shack 2006 with the IF moded to accept a wider FM signal. Now
use a Hamtronix R139.
You can do this with an unmoded (IF) scanner initially, but the limited IF BW
reduces picture quality greatly.
2) Sound card on your PC
3) WxSat http://www.hffax.de/WX_Satellite/WXSat/wxsat.html -or- SatSignal
http://www.satsignal.net/

Recommend the following site for additional info:
http://www.geocities.com/tegwilym/

You'd see the picture quality suffering on the televisions long before the
FM signals would be that severely affected. It appears you are doing
everything
correctly. That leaves two possibilties. The JVC is defective--can you
receive off-air
signals using an antenna on the set? The cable company is having problems
with the
system--try another receiver on the cable.

> Not all of us hams are 300 pound-grrrizly adams-- loner- man-mountains who go and shoot people.<

Our local Rabbi looks like that, but he's a very jovial fellow. Fact is, being big, single, growing a beard, and even owning legally registered guns rank pretty low on the list of indicators predictive of a person who may commit crimes of vengence.

On the other hand, chronic expressions of persecution coupled with habitual threats to initiate adversarial action in order to "set things right" rank pretty high.

In the movie "Falling Down", the professionally-dressed bespectacled character portrayed by Michael Douglass didn't look like Grizzly Adams at all, but he did have an axe to grind!

So, apparently, did Mr. McDermott. Despite holding down a full time job, the Boston Globe reported he was in the process of losing everything --including his car, a big chunk of his future earning potential, and therein his ability to pay rent. One need not be a "shrink" to understand how little of life those realities must leave a clinically depressed man to cling to.

Now, it appears, the very institutions so deeply invested in stealing away his life have suffered hideous and irrepairable losses, and are concurrently stuck with the legal obligation to clothe, feed, and house him for the remainder of his life (note that McDermott didn't attempt to take his own life or confront police officers when they arrived on the scene, and note that there's no death penalty in Mass). For a hopeless and deeply troubled soul, this grotesque solution might have looked like an attractive turn of fate.

If, indeed, Mr. McDermott of Bartlett St. in Haverhill is KB1EVA, it's sad that he has been stereotyped by Dr. Cohen, a man who ought to know better. It's even sadder that no one in our fraternity was close enough to McDermott to intervene and prevent this tragedy from ever happening.

Bigdad wrote:
"---I don`t think Morse is the measure of the man and should not hamper the growth of our hobby.

As all citizens deserve equal rights, benefits, and treatment under the law, these should be regulated only in the public interest, convenience, and necessity, (PICON) as shown in the old communications act of 1934. Most of the act was in the spirit of public safety. Humans shouldn`t interfere with vital communications. Commercial monopolies which are natural results of restricting access to a limited resource also had to be regulated.

Access to radio frequencies should be as unregulated as is practical.

Ruling CW permissible on any ham band, anywhere, at anytime is nonsense. Emergency access is already allowed to anyone on any frequency in dire emergencies. You don`t have to be a ham to try to save a life with radio.

To allow universal CW access is akin to allowing horsemen to excercise their hobby on any public trail, pathway, or road, because there have almost always been horsemen around, though now superseded by motorists.

Morse is now obsolete and quickly started to become so with the first practical voice modulation. Just as the telephone replaced telegraph for practical purposes, voice modulation makes CW obsolete.

In the early days of radio, sinking ships gave radio and its telegraphers fame and celebrity. They deserved it.

Hams at times provided the only communications available, by CW, in early times, and they were the only game in town. They too gained celebrity, and deserved it.

Face it! It`s mostly over. Too many cell phones are around in most emergencies for a ham to be indispensable. Anyone can use wireless with no license, just pay the monthly fee.

Ham radio is a hobby, and CW is just a niche within this hobby which deserves no more than encouragement for its preservation. People need fun and CW is fun for some. It is also nice to have demonstrations of how it used to be. It makes you appreciate the present. Horsemanship is similar in its status as a hobby. It is fun and profitable for some, but doesn`t deserve first consideration in accommodations. There are too many other users of the facilities who want to use other equipment.

Best regards, Richard Harrison, KB5WZI

12" may be a bit short, I would start with a 14" or longer adjustable rod. What I normally do is to take a piece of tubing that will allow the center conductor to slide through with a snug fit (10"long) and simply run the center conductor of the coax through it.(strip off at least 20") The end of the tubing closest to the center point of the antenna is held by a piece of insulating material. I then take another piece of tubing (10") that will slide over the first and and make a bracket that hooks to the sliding piece and the boom. The amount of capacitance between the coax center conductor and the tubing will give you enough C, then move the sliding piece back and forth for best SWR. I would start at 15" and work my way in. When done you can cut off the excess center conductor about 1" past the end of the gamma rod. The braid of the coax is connected to the center of the boom with a nut, bolt and round lug. Cover this connection with a silicon sealer.

5397. snake antenna variants

Newsgroup: rec.radio.amateur.antenna
Date: 2000-12-31 18:46:02 UTC
From: inagaddadavida@webtv.net
Message-ID: <29958-3A4F7EEA-33@storefull-116.iap.bryant.webtv.net>
Source record: 173453

i have been using a "snake" antenna made of 100 feet of coax, terminated with a 75 ohm resistor. the termination is supposed to keep a resistive load no matter what the frequency presented. the use of coax shield as the element is supposed to act as some sort of impedance transformer. the shield picks up signal but yet it is its own transmission line at 75 ohms. this holds the impedance to 75 ohms when the random length of antenna should be thousands of ohms. is this all crap? most people tell me that it is crap, but this antenna works very well for rx. i have several antennas to use but i only seem to use the snake anymore. (i have a severe noise problem here) essentially i have a random wire with coax shield as the element. it works better with a earth ground but thats not portable. so i thought about a counterpoise, to improve ground but no need to drive a rod.......then i thought "what is a random wire with a counterpoise? its a dipole!" a snake dipole? hmmmmmm. what do you guys think of all of this? is there any benefit or difference between the counterpoise and element design (unbalanced hertz type?) or the dipole, with both elements being equal coax elements? (balanced antenna) what impedance at the feed point? (2 elements at 75 ohms each, connected to a feedline. 37 ohms? 150 ohms?) will the dipole be as wide band as the random wire? ouch! owww! my head hurts! opinions please......

Just a guess... but by looking at the headers,
it would appear that "NC" is in Australia.

Don't know what services available there, NC
but the first respondent was correct. Buy an
amateur 70 cm antenna and modify it, or
home brew a small quarter-wave ground plane.

Details in any good antenna book.

Most non-CW folks are reacting like little children at the dinner table, "I don't like that", in spite of the fact they have not spent any time on CW. Just as you found you really liked green beans once you tried them, CW is also enjoyable!

It's in the ARRL Antenna Book. Seems the best one can do is
spacing of 1/4WL with a phasing of 135 deg for a 4.5dB gain.

This man is in AUSTRALIA.
The OZ CB band in the UHF has been there for 30+ years.
Same basic Idea as the US CB. The US's Class "A" CB (now GMRS) was supposed to
be like this.
It's just that the UHF frequency band placement avoided the fiasco that the
FCC's placement of CB on 27 MHz created.
UHF guaranteed that the service stayed local and low power.

My 1963 ARRL Handbook is marked $3.50

My 1968 ARRL Antenna book is marked $2.50

When I first started buying QST at newsstands in about 1949, the
Lifetime ARRL membership fee was a whopping $20 total. Somebody with
some of these old issues could look back and see just when it started
up - I think it was within a year or two of that.

Just shows how we no longer have dollars - they are now dollarettes.

Jim,
A snake antenna is a receive only antenna. It was originally
meant to be a full wave length at what ever frequency/band you
find of interest, and terminated in a resister of the same value
as the cable's characteristic impedance (RG-58=50 ohm, RG59=75,
etc). The primary 'draw' of a snake antenna is that it's quiet.
Since it's only used for recieving, and since it's usually made
from 50 ohm coax, you really don't need to worry about impedance
matching to a receiver. If you decide to make a 'dipole' out of
two snake antennas, I still wouldn't worry about imdepance, receivers
usually aren't all that 'picky' about matching. As to how well
it works? Who knows, give it a try and tell us.
'Doc

Isn't the 18v a simple vertical with a loading coil, tapped, at it's base?
IIRC, you move the tap for each band. I had one in the mid '70s, worked my
first dx (an OA5) on it as a novice. It wasn't a half bad antenna for
10-20 and it seemed ok for 40, though nothing special.
I used it 'cuz it was a gift from a friend and for the money worked fine.
When I got some decent dipoles up, they did a better job and I abandoned
it. It was a pain in the neck to run out to the antenna and set the tap.

Hi OM,

As for the images. I notice the 120 Hz signal you have in your image (60 Hz power component no likely). The interference's waviness appears to be a beat note with your own 60 Hz mains (or the 30 Hz ref. for the video). This would suggest the interference is remote. Remote is a rather tenuous label given that it could be an aquarium heater next door.

So many possible problems here barring correct grounding.

First problem is the presumption that your gear connected to wall socket finds ground. Perhaps... and in the worst possible way. Put bluntly, this is a wild card.

How to troubleshoot this?

First: make sure you can re-establish the problem with the minimum of gear and connections on a regular basis. Many of the steps of troubleshooting will seem to fix the problem while also killing the signal (the operation was a success, but the patient died).

Second: attempt to replace the suspect source/path with a 50 Ohm load and observe if the interference goes away or remains. IMPORTANT: Take care not to disturb ground paths while you are opening and loading the signal path. Repeat this from the antenna connection (at the antenna) back toward the receiver. Continue this with a 600 Ohm resistor when the signal is converted to audio and track back towards the computer. This will separate over the air sources from nearby sources.

Third: (or concurrent with step two above) break the ground path and observe if the interference goes away or remains. This can be very frustrating if you lose track of all the combinations of ground and signal condition (in other words write down all the tests and results so you don't get wrapped around the axle).

Alternative: replace all sources of power with freestanding batteries and break ALL ground paths (do not open shields however) and observe if the interference goes away or remains. The sense of this is that

from the antenna to the computer there are only ever two wires conducting (batteries leads don't count) and no path to ground exists until we hit the computer (with a humongous wire to ground and the cold side of the AF tied to it). This is more complex in that the interference may have gone away and your job is to add it back carefully (so that you can isolate the source).

The steps above are about the simplest way to describe the job before you. They encompass a lot of territory, and yet leave much to be explored. Most of these steps presume the interference is coming from you (a ground loop).

If on the other hand tests reveal the interference is remote, you need to find a way to reject the signal. One option would be to build an array or bank of antennas. By phasing them, you could reject the interference, however, given that your signal is moving (circling over you) phasing would be problematic. Others here in this board may have some discussion in that venue perhaps.

This may well devolve to an isolation transformer in the audio path, but even here you have to pick the right point. Also, be aware that there are isolation transformers for 120VAC too (I use one for my shack) that allow you to control ground absolutely and kill power-line borne noise.

Please note this could take a lot of time. Good Luck :-)

IMHO, the value is diminished --as a general EE ref--compared to other pubs, especially CD-ready ones. Example? ART OF ELECTRONICS by Horowitz and Hill.

In 1962, I am of the opinion the handbook was the primo resource. I bought my first one in 1967 for $5.00. Had all the tube configs in it:-)

Glow lil' glowbug!

Doug DeMaw did a feature on the coaxial snake antenna for QST magazine some decades back. It is a low noise receive only antenna, like a Beverage, and is not for transmitting. I beleive it was intended for 160 meters, and also perhaps 80 meters. The coax is laid on the ground in as straight a line as possible.

Use a handheld scanner tunned to an unused spot in the VHF civil air band
(108-138) to "track down" noise sources. Remember the air band is AM and you
should be able to hear the noise fairly clear. To verify a power pole has a
bad insulator (or wire junction), use a 3Lb{1Kg} (or so) hammer to tap,
(DO NOT SLAM the pole!) a little tap will do. You should be able to hear the
noise change when the pole is taped.
Good luck and expect some very strange looks!

Will the scanner allow me to narrow down the potential poles? In other words,
will the noise change volume as I approach the offending pole? Or must I
hammer on all poles within a mile of my house? ;-)

> Good luck and expect some very strange looks!

Yea.... I'd expect quite a few.
Hope I don't see a group of people in white coats approaching. ;-)

5423. Re: Best Discone Antennna?

Newsgroup: rec.radio.amateur.antenna

Well, let's see:

Cheap discone: Cheap mounting bracket, plated TV type hardware. With only one bracket, might twist in a strong wind. Can rust.
Expensive discone: Cast or machined mounting bracket. Maybe two brackets instead of just one for better wind resistance. Stainless or aluminum hardware.

Cheap discone: Light-weight, thin-walled elements.
Expensive discone: Heavier, thick-walled or even solid elements.

Cheap discone: Elements crimped to screw-in terminations. Susceptible to vibration.
Expensive discone: Elements with built in termination or welded to termination secured with setscrews or jam nuts.

Cheap discone: Short cone and small disc.
Expensive discone: Longer cone and wider disc.

Cheap discone: 100 mhz and up; low band reception via capacitance of elements.
Expensive discone: 80 Mhz and up with auxiliary element resonating in the low-VHF range.

Cheap Discone: Type UHF connection with poor UHF impedance characteristics.
Expensive discone: Type N or BNC connector good through over 1 GHz.

Cheap discone: Buy your own cable or cheap cable provided.
Expensive discone: Length of low-loss cable (relatively) provided.

Difference in use? For VHF-high and up reception, very little! But I will give you an example of a difference that counts; after a year on the mast, (including Massachusetts Winter) elements on my Tandy discone were loose at the crimps; a Diamond merely needed setscrews tightened.

>If, indeed, Mr. McDermott of Bartlett St. in Haverhill is KB1EVA, it's sad
>that he has been stereotyped by Dr. Cohen, a man who ought to know better.

Mr. Littlefield--

I demand that you retract this statement. It is maliciously incorrect.

The only comment I made about McDermott is that there was an apparent discrepancy between dates and e-mail addresses (re: KB1EVA), and thus it was premature to assume they were the same fellow.

I have NO additional information; have not had an interest or desire to pursue it; and have no idea WHY you have made this outrageous statement.

This is your last chance to just DROP ME from your repertoire of people to harrass. Tomorrow is more than just another day. I have publicly made it clear what happens--legally--in the new year.

Rick--JUST--FOCUS--ON SOMETHING--ELSE==> NOT me.

OK?

I wish to thank the many people who have offered friendship, information, and good camaraderie in the last year on this NG.

As Dickens said--'it was the best of times, it was the worst of times'.

Here's to a happy, civil, and fun NG in the year of the space odyssey -- and new millenium!
